## Baseline Characterization of Benchmark Watersheds in India, Thailand and Vietnam

C itation: Wani SP and Shiferaw B (eds.). 2005. Baseline characterization of benchmark watersheds in India, Thailand and Vietnam. G lobal Theme on A groecosystems Report no. 13. Patancheru 502 324, Andhra Pradesh, India: International Crops Research Institute for the Semi-A rid Tropics. 104 pp.

#### Abstract

The project on "Improving M anagement of N atural Resources for Sustainable Rainfed A griculture" (RETA 5812) was executed by the International Crops Research Institute for the Semi-A rid Tropics (IC RISAT) by adopting a consortium approach for technical backstopping of the community watersheds. The targeted ecoregion is characterized by assured annual rainfall of $700-1300 \mathrm{~mm}$ with medium to high water holding capacity soils. Five benchmark watersheds in India, northeast Thailand and northern Vietnam covering the target ecoregion were selected to develop and test the holistic farmer participatory integrated watershed development model with the aim of increasing agricultural productivity on sustainable basis while minimizing land degradation for improving the rural livelihoods. All the five benchmark watersheds in Asia were characterized for socioeconomic parameters by adopting rapid rural appraisals (RRA s) and detailed household surveys using stratified sampling method. The results of biophysical, socioeconomic, characterization as well as inputs and crop productivity are discussed in this report.

This publication is part of the research projects "Improving Management of Natural Resources for Sustainable Rainfed Agriculture" (RETA \# 5812) and "Participatory Watershed Management for Reducing Poverty and Land Degradation in the Semi-Arid Tropics" (RETA\# 6067) funded by the Asian Development Bank (ADB) to ICRISAT.

## Acknowledgments

The financial assistance provided by the Asian Development Bank (ADB) through RETA 5812 and 6067 is gratefully acknowledged. The efforts of the consortium team members from D rought Prone Area Program (DPAP); Bhartiya Agro-Industries Foundation (BAIF) Development Research Foundation; Central Research Institute for Dryland Agriculture (CRIDA); M V Foundation of India; Vietnam Agricultural Sciences Institute (VASI), H anoi, Vietnam; Department of Agriculture (DOA); D epartment of Land Development (DLD); and Khon Kaen University (KKU ), Thailand; are greatly appreciated. At all the benchmark sites, teams of scientists from NARS and ICRISAT are involved in undertaking research; their efforts are also acknowledged. The contributions from Drs. HP Singh (CRIDA), N arongsak Senanarong (DOA), TD Long (VASI), BR Patil (BAIF), are duly acknowledged. The support from ICRISAT staff, M r Anand Vadivelu and Mr H abeeb; and the secretarial support of Mr KNV Satyanarayana are appreciated. The contribution from farmers is greatly acknowledged; they are important partners who provided necessary information for the project.

The opinions expressed in this publication are those of the authors and do not necessarily reflect those of ICRISAT or ADB. The designations employed and the presentation of material in this publication do not imply the expression of any opinion whatsoever on the part of ICRISAT or ADB concerning the legal status of any country, territory, city, or area, or of its authorities, or concerning the delimitation of its frontiers or boundaries. Where trade names are used this does not constitute endorsement of, or discrimination against, any product by ICRISAT or ADB.

## Introduction

This report covers the benchmark socioeconomic surveys conducted at five benchmark locations in three countries (India, V ietnam and Thailand) under the project entitled "Improving $M$ anagement of Natural Resources for Sustainable Rainfed Agriculture" (RETA \# 5812) funded by the Asian D evelopment Bank (ADB), M anila, The Philippines. The International Crops Research Institute for the Semi-Arid Tropics (ICRISAT), Patancheru, India, is the implementing agency for this regional technical assistance project.

Any project/program, whether small or big, far-reaching or limited in scope, regional or national, begins with a needs assessment. Priorities are made and needs are defined by the project leaders. For this to be done, information is needed, which is the basis of all planning; without an appropriate assessment of the prevailing conditions and resources, planning will fail. To have an assessment, data on population, environment, agriculture, industry, the peoples' current economic situation and their needs, characteristics and professional backgrounds, and so forth are needed. Needs assessment is done in all the benchmark sites.

## Collection of information

The cycle of planning, monitoring and evaluation begins with a needs assessment and the collection of information relevant to desired goals and indicators to be measured. The information gathered must be applicable to the needs, the reality, the environment, the socioeconomic characteristics and the services already available in an area to build the necessary foundation for the plan. This becomes more important in view of the limited resources.

Many different tools and methods are used for research and data collection. These included questionnaires, interviews, focus group meetings, group discussions, observations, inspection and secondary sources such as reports and documents. Each tool helps in monitoring and evaluating, but it is always good to diversify rather than use only a single tool. The tools have been prepared by the social scientists depending on the project and issues to be evaluated.

The method used here is the Participatory Rural Appraisal (PRA) - an exercise that was carried out by involving the concerned community in defining needs. The PRA gives a quick initial idea. More detailed surveys can be conducted on this basis.

## Baseline data survey

At the outset of the project, a baseline survey was carried out to generate the necessary information on the biophysical and socioeconomic environment, context and conditions of the villages and communities. This initial data set builds the basis for subsequent monitoring and evaluation activities. Potential change on the economic, ecological and social system is monitored using the baseline data set. A baseline survey is therefore a precondition in assessing the project impacts and effectiveness.
The baseline survey is the starting and reference point (counterfactual) upon which achievements are judged at any stage of the project process. Baseline surveys are the scientific basis used to assess and measure progress and to assure the availability of qualitative and quantitative data. Baseline data therefore facilitate and/or assist management tasks, including research processes policy and planning decisions. This gives a first insight into the overall biophysical and economic situation of the village or watershed.

In a baseline survey, qualitative and quantitative data were collected. Q uantitative data included socioeconomic data on production, yields, population, education and so forth. Qualitative data is not measured in numbers, but in terms of efficiency, satisfaction, effectiveness and other related criteria.

The collected information allows those involved in the project to understand the initial livelihood conditions of the people, and what needs to be done to reach the goal of improving the livelihoods of the poor. This report serves as a reference against which the successes of the project can be measured in the future.

## Project goals, purpose, objectives and scope

The objectives of the project are to (1) increase the productivity and sustainability of the medium and high water-holding capacity soils in the intermediate rainfall ecoregion, and (2) develop environmentfriendly resource management practices that will conserve soil and water resources. The study is focused on the intermediate rainfall ecozones in central India, northeastern Thailand, and northern Vietnam where the annual rainfall is about $800-1300 \mathrm{~mm}$ and where the soils have a relatively high water-holding capacity.

The scope of the project includes benchmark socioeconomic surveys, strategic research, on-farm research and human resource development.

At selected on-farm benchmark watershed sites (three in India, one each in Thailand and Vietnam), detailed socioeconomic surveys, PRAs and rapid rural appraisal (RRA) techniques were used for studying major socioeconomic, biotic, and abiotic constraints to sustainable crop production. Based on the PRA and RRA studies conducted, the constraints and general findings were reported in the first annual report submitted covering the period of January-D ecember 1999.

## Partnerships

The participating developing member countries (DM C s) of the project are India, Thailand and V ietnam. O ur partners for carrying forward the research and development agenda of the project are as follows:

## International institution

- M anagement of Soil Erosion Consortium (M SEC) project, International Board for Soil Research and $M$ anagement (IBSRAM), Thailand.

## Developing member country institutions

## India

- Central Research Institute for Dryland Agriculture (CRIDA), Indian Council of Agricultural Research (ICAR), Santoshnagar, H yderabad.
- Indian Institute of Soil Science (IISS), ICAR, Bhopal, M adhya Pradesh.
- Jawaharlal N ehru Krishi Vishwa Vidyalaya (J N KVV ), Indore, M adhya Pradesh.
- N ational Remote Sensing A gency (N RSA), H yderabad, India.
- Drought Prone Area Program (D PAP), G overnment of Andhra Pradesh.
- Bhartiya A gro-I ndustries Foundation (BAIF) D evelopment Research Foundation, Bhopal, M adhya Pradesh (non-governmental organization).
- M Venkatarangaiah Foundation (MVF), Hyderabad, Andhra Pradesh (non-governmental organization).

## Thailand

- Royal Department of Agriculture (DOA), Bangkok
- Royal Department of Land D evelopment (DLD), Bangkok
- K hon K aen University (KKU), Khon K aen, Thailand

## Vietnam

- Vietnam Agricultural Science Institute (VASI), H anoi

## Advanced research institutions

- M ichigan State U niversity (M SU ), East Lansing, M I 48824-1325, U SA
- University of G eorgia, G riffin, Georgia 30223-1797, U SA

# Adarsha Watershed, Kothapally, Andhra Pradesh, India 

Matthew Hughes, Charlotte Donald, SP Wani, TK Sreedevi and K Sailaja

## Location

Andhra Pradesh (AP) is the fifth largest state in India, in terms of both area and population, bounded by M adhya Pradesh and Orissa in the north, the Bay of Bengal in the east, Tamil N adu and Karnataka in the south, and $M$ aharashtra in the west. Andhra Pradesh forms the major link between north and south of India. The population of the state is 7.57 million according to the 2001 census and the sex ratio is 977 females per 1000 males, which is higher than the country's average of 929 . The literacy rate of the country is $35.74 \%$ - AP is ranked $25^{\text {th }}$ among the 35 states and union territories. The literacy rate among males is $47.28 \%$ and among females is $23.92 \%$ (N CAER 2001). The per capita state domestic product in 1990-91 at 2001 prices was Rs. 5215 (Shiv Kumar 1991). The climate is hot and humid with an average rainfall of 925 mm . The state of AP consists of 23 districts: (1) Andhra, the coastal region is made up of nine districts; (2) Rayalaseema, the interior region consisting of four districts; and (3) Telangana region consisting of the state capital, H yderabad, and nine adjoining districts. The Telangana zone comprises $42 \%$ of the state and lags behind the other two regions in terms of socioeconomic and demographic indicators. O ne of the benchmark sites, A darsha Watershed in Kothapally village, is located at Shankarpally mandal, Ranga Reddy district, in Telangana region of A ndhra Pradesh, India (Figure 1). The Kothapally village was selected after visiting and inetracting with farmers in three villages (Appendix 1).
The village Kothapally is situated 50 km from H yderabad, the state capital of Andhra Pradesh. The closest markets are the towns of Chevalla and Shankarpally, located about 20 km away from the watershed. The population of the village is 1492 with 274 households. The total land area is 464 ha, with an average landholding per household of 1.7 ha. The Kothapally watershed is characterized by undulating topography and black soils.

Figure 1. Location of K othapally village in Shankarpally M andal, Ranga Reddy district, Andhra Pradesh.

## Micro-watershed

For detailed hydrological and productivity measurements, a 30 ha micro-watershed based on the topographic survey was delineated. In this micro-watershed, the effect of soil and water conservation measures on runoff, soil loss, agricultural productivity and soil quality was studied. Figure 2 shows the location of the micro-watershed within the Adarsha Watershed.

Figure 2. Designated micro-watershed in K othapally village.

## Methodology

Two hundred and seventy four households in the village were divided based on their landhodling size and the households were classified into three groups: small (less than 1 ha [excluding landless]), medium (1 to 2 ha ) and large landholders (greater than 2 ha ). The small landholders, medium landholders and large landholders constituted $50 \%(137), 22 \%$ (60) and $27 \%$ (73) of the households, respectively.

Twenty percent of the households were selected for a detailed survey. Accordingly, fifty-five families from different landholding classes were selected proportionately. Out of a total 274 households, four (1\%) were landless in the village. The $20 \%$ proportional sample constituted 28 small landholders, 12 medium landholders and 15 large landholders. In addition, 18 households who had land in the microwatershed were also selected for a detailed survey. The households from each landholding group were selected randomly using random number tables. In total, 73 families were surveyed in detail using structured questionnaires (Appendix 2). The data collection was completed within 3 months.

## Social structure and land tenure

## Distribution of land and landholdings

In Adarsha Watershed at Kothapally, Iarge landholders (greater than 2 ha Iand) who were about 27 percent of the total population possessed 69 percent of the farmland with an average landholding of 4.29 ha. M edium landholders ( 1 to 2 ha) who were about 22 percent of the total population held 16 percent of the farmland with an average landholding of 1.25 ha. On the contrary, small landholders (less than 1 ha) who constituted 50 percent of the households held 15 percent of the farmland with an average landholding of 0.525 ha (Table 1).

Table 1. Landholdings of small, medium and large landholders in K othapally.

| Landholders | No. of households | Total land area(ha) | Average landholdings(ha) |
| :--- | :---: | :---: | :---: |
| Small (<1.0 ha) | $136(50)^{*}$ | $71.40(15)$ | 0.52 |
| M edium (1.0-2.0 ha) | $60(22)$ | $75.30(16)$ | 1.25 |
| Large ( 2.0 ha) | $74(27)$ | $317.60(69)$ | 4.29 |
| Total | 270 | 464.30 | 1.72 |

* Values in parenthesis indicate percentages.

## Family composition

In K othapally, the average family size was seven consisting of four males and three females (Figure 3). With regard to age structure (Figure 4), the family consisted of one child (up to 5 years), two young adults (6-18 years) and four adults (19-55 years) in the village.

Figure 3. Family composition in Kothapally village.

Figure 4. A ge structure in $K$ othapally village.

## Social strata

With a total village population of $1492,54 \%$ of the population belongs to backward communities (BC), $15 \%$ to minority community (M uslims), $20 \%$ to scheduled castes (SC) and $9 \%$ to other castes as shown in Table 2 (Figure 5). It needs to be noted that only landholders were surveyed, and while these figures should be a fair representation of those who possessed land, the data did not include landless households.

Table 2. C aste wise distribution of farm households in Adarsha Watershed.

| Category | ST | SC | BC | M inorities | OC | Total |
| :--- | :---: | ---: | :---: | :---: | :---: | ---: |
| $<1.00$ ha(Small landholders) | $4(3)$ | $20(15)$ | $64(47)$ | $17(12)$ | $31(22)$ | 136 |
| $1.00-2.00$ ha(M edium landholders) | - | $8(13)$ | $38(63)$ | $5(8)$ | $9(15)$ | 60 |
| $>2.00$ ha(L arge landholders) | - | $7(10)$ | $35(47)$ | $6(8)$ | $26(35)$ | 74 |
| Total | $4(2)$ | $35(13)$ | $137(51)$ | $28(10)$ | $66(24)$ | 270 |

N ote: ST = Scheduled tribe, SC = Scheduled caste, BC = Backward caste, OC = O ther caste.Values in parenthesis indicate percentages.

## Caste and education

Education levels are discussed here across castes as caste plays an important role in the level of education of a person in India. Over 80 percent of the scheduled castes (SC) in Kothapally had no school education, while 10 percent of them had been to elementary school, and another 10 percent had been to high school. N early 70 percent of the backward castes (BC s) had no school education, and almost 20 percent had been to elementary school. Ten percent of the BC s had been to high school and less than 5 percent had been to college. Sixty percent of the other castes had no schooling, while the rest 40 percent had been to elementary school. O ver 60 percent of the Muslims had no school education, and 25 percent of them had been to high school. Some 13 percent of the M uslims had been to a tertiary institute (no formal education).

Beteille (1974) stated that literacy and education might be unevenly distributed in an agrarian society and the data collected in Kothapally supported this statement with regards to inequalities between sexes and between castes. The above data revealed that the education level increased along the caste hierarchy. This pattern was seen throughout India, which highlighted the fact that educational

Figure 5. C aste and religious composition of (a) K othapally watershed and (b) micro-watershed.
opportunities were traditionally been taken up by higher castes. M. Venkatarangaiah Foundation (MVF), the NGO in Kothapally Village, is trying to address this situation through an intensive program to abolish child labor and child marriages, and to provide educational opportunities for lower castes. M VF's presence in K othapally seems to have contributed to increased child enrollment in local schools, especially preventing the children being taken out of school for domestic and field works by the lower castes. It would take some time for the educational patterns to change in K othapally, and it remains to be seen whether exposure to basic education prompts the lower castes to continue high school and college studies.

## Gender and education

Education levels were also studied in terms of gender as it is a known fact in India that gender always played a major role in the level of education a person attains traditionally. Females are traditionally neglected and are not encouraged to go to schools. Rather they are sent for work to earn money for the family. This fact was evident in Kothapally village. Nearly $40 \%$ of males in the village received some form of education, while less than 10\% of females had been to school. The discrepancy between the sexes was striking, with males having received some form of education when compared with females. A major part of M VF's programs was focused on the girl-child by providing opportunities to attend schools and breaking the cycle of illiteracy that is perpetuated from generation to generation. G irls' education is key to women's empowerment.

## Education levels within family

On an average, there were three people per family in Kothapally without any form of educational background, one child per family at preschool, two young people at elementary school and one family member at high school (Figure 6).

## Caste and land tenure

The BC s were the dominant landowners in Adarsha Watershed, K othapally, with the OCs owning relatively small percentages of the small and medium landholdings. This finding supported other

Figure 6. Education levels at Kothapally village.
studies, which showed that at the local level the dominant landowning group often was at the middle and not at the top of the caste hierarchy (Beteille 1974).

The backward castes constituted 47 percent of the small landholders and held 51 percent of the total land held by the small landholders. The scheduled castes (SC s) constituted 15 percent of the small landholders and held 13 percent of the land held by the small landholders (Tables 2 and 3). The OCs constituted 22 percent of the small landholders and held 20 percent of the land held by the small landholders (Tables 2 and 3). Among the medium landholders, BC s comprised 63 percent and held 65 percent of the total land held by the medium landholders. SC s constituted 13 percent of the total medium landholders and held 13 percent of landholdings. Amongst the large landholders, BC scomprised 47 percent of the landholders and held 37 percent of the land held by the large landholders. The O C s comprised 35 percent of the large landholders and held 51 percent of the total land held by the large landholders. M ean land held across the landholding groups was least at 0.44 ha per household for STs followed by 1.1 ha for SC s, 1.15 by minority communities, 1.49 ha by BC s and 2.85 ha by OC s (Table 4). A mongst the large landholders, O C s held 7.24 ha per household as against 2.74 to 3.39 ha by SC s, minorities and BCs. Amongst the medium and small landholders, land held by BCs, SC s and minorities is of a similar magnitude as that of the land held by OCs (Table 4).

## Gender and land tenure

Landholders were dominantly male; $80 \%$ of the land in K othapally village and $85 \%$ of the land in the micro-watershed area was owned by males. The land owned by female-headed households mainly comprised widowed women whose sons had not attained majority. Daughters could claim the land when it was included in the dowry, but then this became the property of her husband and his family. The dominance of males in terms of land ownership, combined with higher educational attainment indicated that the balance of power was strongly weighted in favor of males.

Table 3. C aste wise landholding (ha) in Adarsha Watershed.

| Land (ha) | ST | SC | BC | M inorities | OC | Total |
| :--- | :---: | :---: | :---: | :---: | :---: | ---: |
| $<1.00$ | $1.76(2.5)^{*}$ | $9.67(13)$ | $36.33(51)$ | $9.35(13)$ | $14.30(20)$ | 71.41 |
| $1.00-2.00$ | - | $9.56(13)$ | $48.72(65)$ | $6.18(8)$ | $10.83(14)$ | 75.29 |
| $>2.00$ | - | $19.19(6)$ | $118.63(37)$ | $16.62(5)$ | $163.14(51)$ | 317.58 |
| Total | 1.76 | $38.42(8)$ | $203.68(43)$ | $32.15(7)$ | $188.27(41)$ | 464.28 |

* Values in parenthesis indicate percentages.

Table 4. Average landholding (ha) per household in different landholding sizes and caste distribution.

| Landholdings | ST | SC | BC | M inorities | OC | Total |
| :--- | :---: | :--- | :--- | :---: | :--- | :--- |
| Small ( < 1 ha) | 0.44 | 0.48 | 0.56 | 0.55 | 0.46 | 0.52 |
| M edium ( > 1-2 ha) | - | 1.2 | 1.28 | 1.24 | 1.2 | 1.25 |
| Large (> 2 ha) | - | 2.74 | 3.39 | 2.77 | 7.24 | 4.29 |
| Total | 0.44 | 1.1 | 1.49 | 1.15 | 2.85 | 1.72 |

## Agriculture - Land Use and Crop Production

## Irrigation

The irrigated area consisted of $20 \%$ of the total area for small landholders, while it was only $10 \%$ in the case of medium landholders. The large farmers had a higher percentage (40\%) of the owned area.

The micro-watershed showed a different pattern of irrigation. O nly 10\% of the small landholders had irrigated crops, while more than $30 \%$ of medium landholders had irrigation facility. Large landholders in the micro-watershed had no irrigation at all (Figure 7).

## Cropping pattern in the 1998 rainy season (kharif)

The major sole crops grown were paddy and cotton, and intercrops grown were sorghum/ pigeonpea. Paddy being the staple food crop occupied 41.65 ha ( $22.50 \%$ of the cultivated land). The next major crop in terms of acreage was cotton which was cultivated in medium black to deep black soils in 33 ha ( $17.83 \%$ of the land). C otton is an important cash crop which is grown in black soils ranging from soil depths greater than 90 cm . Black soils with high clay content provided a suitable physical environment for greater moisture retention and less percolation losses. Among intercrops, sorghum/pigeonpea occupied 21.34 ha (11.53\%) of the area. A large diversity in the cropping pattern in mixing various combinations of crops is shown in Table 5. Fallow/waste land constituted $11.83 \%$ of the area. Figure 8 shows the cropping pattern during the rainy season in 1998.

## Cropping system - 1998 postrainy season crop (rabi)

The major crops grown during rabi season on residual soil moisture or with irrigation were vegetables and chickpea. Vegetables were cultivated in deep black soil of greater depth than 90 cm in an area of

Figure 7. Land use (dry or irrigated) by small, medium and large landholders of K othapally village.

Figure 8. C ropping pattern, rainy season 1998.

## Table 5. Diversity of crops grown in Adarsha Watershed, K othapally, rainy season, 1998.

| Cropping system | Total area in ha | Percentage |
| :--- | :---: | ---: |
| Sorghum/pigeonpea + beans | 0.06 | 0.03 |
| Sorghum/pigeonpea + cotton + turmeric | 0.08 | 0.04 |

14.84 ha (15.33\%) followed by chickpea in medium black to deep black soils in an area of 28.7 ha (29.65\%) and in a few pockets of Choudu soils, where the soil depth was up to 50 cm . The analysis revealed that the cropping pattern in rabi was determined by the availability of residual soil moisture or irrigation facility as shown in Table 6. Figure 9 shows the postrainy season cropping pattern in Adarsha Watershed in 1998.

Figure 10 illustrates the season-wise cropping pattern of small, medium and large landholders. Majority of small, medium and large landholders (31 percent, 43 percent and 16 percent,

Small Landholders

Rainy season

Postrainy season

Figure 10. Cropping pattern of small, medium and Iarge landholders in rainy and postrainy seasons at K othapally watershed.
respectively) grew sorghum crop during the rainy season. Rice (kharif), sorghum and pigeonpea were the major crops among the large landholders and sorghum crop was the major crop for small and medium landholders.

## Landholding

The average landholding of 73 surveyed farmers was 2.34 ha with 0.41 ha of irrigated and 1.93 ha of dry land.

## Soils

The soil types ranged between shallow black soils (less than 50 cm ), medium black soils ( 50 to 90 cm ), deep black soils (greater than 90 cm ), red soils (less than 50 cm ) and sodic soils (less than 50 cm ). Figures 11 and 12 show the soil types - the deep black soils are more fertile with greater clay content and greater moisture retention. Medium-to-deep black soils in the postrainy season had high productivity where crops were taken up on residual moisture.

Figure 11. Soil Types in Adarsha Watershed, Kothapally village.

Figure 12. Soil Depth profile in Adarsha Watershed, K othapally village.

## Groundwater level

The average depth of the 56 wells surveyed is 7.35 meters. The groundwater levels showed a high degree of variability with depths ranging from 2 meters to 18.65 meters, as shown in Table 7. The variation in the groundwater depth and the amount of water harvested is based on the cropping pattern and other factors such as soil type, crops grown, topography (relief), runoff and geological factors of the area.

## Productivity within land sizes

The productivity for each crop within small, medium and large landholders has been tabulated in Table 8. The sample sizes for small, medium and large landholders were 27, 22 and 5 farmers, respectively.

## Crop productivity in Kothapally village

The analysis of Table 8 revealed that the productivity of rice ranged between $266.7 \mathrm{~kg} \mathrm{ha}^{-1}$ and 2400 kg ha- ${ }^{-1}$ for small landholders, while conversely the large landholders had a much lower range of $187.8 \mathrm{~kg} \mathrm{ha}^{-1}$ to $941.2 \mathrm{~kg} \mathrm{ha}^{-1}$. The average productivities in small, medium and large landholders were $2830 \mathrm{~kg} \mathrm{ha}^{-1}, 3090 \mathrm{~kg} \mathrm{ha}^{-1}$ and $1660 \mathrm{~kg} \mathrm{ha}^{-1}$, respectively. A similar trend was also observed in the case of pulse crops. In the case of cash crops, the productivity of cotton among small landholders ranged between $380.95 \mathrm{~kg} \mathrm{ha}^{-1}$ to $1384.6 \mathrm{~kg} \mathrm{ha}^{-1}$ with an average of $210 \mathrm{~kg} \mathrm{ha}^{-1}$. Among medium landholders, it ranged between $333.3 \mathrm{~kg} \mathrm{ha}^{-1}$ to $977.8 \mathrm{~kg} \mathrm{ha}^{1}$ with an average of $1430 \mathrm{~kg} \mathrm{ha}^{-1}$ and in large landholders the range was $170.9 \mathrm{~kg} \mathrm{ha}^{-1}$ to $520.8 \mathrm{~kg} \mathrm{ha}^{1}$ with an average of $670 \mathrm{~kg} \mathrm{ha}^{-1}$. In medium landholders, the turmeric crop recorded a highest productivity of $11,000 \mathrm{~kg} \mathrm{ha}^{-1}$ whereas 842.5 kg ha ${ }^{1}$ and 495.5 kg ha- ${ }^{-1}$ of turmeric productivity was recorded in the case of small and large landholders, respectively. In vegetable crops such as beans and tomato, small and medium landholders recorded highest productivity means ( $551 \mathrm{~kg} \mathrm{ha}^{-1}$ to $327.8 \mathrm{~kg} \mathrm{ha}^{-1}$ ), respectively.

Table 8. C rop productivities ( t ha ${ }^{\mathbf{1}}$ ) in K othapally village.

| Land-holders | Rice | Turmeric | Sorghum | Pigeonpea | Black G ram | Cotton | Beans | Tomato O ther C rop |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Small | 2.83 | 2.10 | 1.47 | 0.19 | 0.83 | 0.21 | 0.79 | - | 0.33 |
| M edium | 3.09 | 2.75 | 1.19 | 0.15 | 0.57 | 1.43 | 1.37 | 0.81 | 0.74 |
| Large | 1.66 | 1.23 | 0.54 | 0.13 | 0.25 | 0.67 | 0.19 | 0.75 | 1.33 |

## Inputs

## DAP and urea

The majority of farmers used DAP and urea fertilizers. The amount of DAP (Figure 13a) and the urea (Figure 13b) applied per hectare fell sharply as the farm size increased.

## Potash and super phosphate

The nutrients were only applied to paddy. The amount of potash (Figure 13c) and super phosphate (Figure 13d) applied declined with the increasing land size. In general, within A darsha Watershed, there was a rapid decline in applied amounts, with small increases in landholdings of about 1-2 ha. As the Iand size increased in Kothapally Watershed, the amount of treatment per hectare remained between 15 and 75 kg . Within the micro-watershed, three farmers who were using potash and super phosphate indicated a decline in application per hectare with the increase in farm size (Figure 13).

## Farmyard manure and compost

The two inputs - farmyard manure (FYM) and compost - showed a variation in the level of utilization among farmers. In the Adarsha Watershed, K othapally, there was a general decline in the amount of FYM (Figure 13e) applied per hectare within the small landholdings. The most significant anomaly was application of nearly $6250 \mathrm{~kg} \mathrm{ha}^{-1}$ of FYM in a plot of about 5 ha. Another slight variation in this trend occured for a plot of about 10 ha where approximately $1250 \mathrm{~kg} \mathrm{ha}^{-1}$ was applied. C ompost used showed a decline similar to that of fertilizer with increase in cultivated land (farm size) (Figure 13e).

## Weedicides and insecticides

Within the K othapally Watershed, weedicides (Figure 13f) and insecticides (Figure 13g) were applied in varying amounts amongst the small landholdings. O verall, a general decline in the use of weedicides and insecticides was noted in Adarsha Watershed and micro-watershed with the increased landholding. The micro-watershed showed a sharp drop in weedicides and pesticides in the case of farmers owning up to one acre, and a gradual decline with increasing land size.

## Caste and livestock possession

Backward castes possessed more number of bullocks, both local and improved breed, milch cows, young stock of cattle and buffaloes, goats, sheep, poultry and she buffaloes (Table 9). The possession of livestock by other castes is found to be very meager except for muslims who held more number of sheep at the time of survey.

Table 9. N umber of livestock possessed by the families based on their caste.

## Reasons for inverse relationship - causative factors

## Irrigation

The study indicated an inverse relationship between farm size and the proportion of total farm area under irrigation. The hypothesis is that this is an important technical factor for the inverse relationship between farm size and productivity. It is difficult to draw a direct relationship between proportion of irrigated area and productivity in Kothapally. The mean proportion of irrigated land per household did show a general decrease with increasing farm size. The mean proportion of small, medium and large farms being $0.84,0.44$ and 0.45 . H owever, because the absolute numbers of farms provided with irrigation within the small and medium size groupings were small, this may be misleading. D espite these uncertainties, the relatively high availability of family labor per hectare on small farms might enable them to devote more labor to the creation and maintenance of irrigation facilities which, in turn, improves the quality of the soil. The availability of family labor on small farms was relatively high compared to the other farmers in K othapally.

## Labor

The availability of the labor was a major constraint for crop production in Adarsha Watershed, Kothapally. This was especially true during peak times such as sowing and harvesting, and if major labor shortages existed, then great losses in terms of productivity and profits occur. Every respondent who required additional labor outside the family stated that a labor shortage existed in Kothapally. However, this problem was more serious for larger landholders. Family size from small to large landholders remained fairly constant and so a relationship of decreasing labor availability per hectare with increasing land size was seen. The mean number of family labor per hectare in Kothapally for small, medium and large landholders was 8, 3 and 1, respectively. An instructive example was the case of chickpea crop where the farmers preferred to sell the crop at the green pod stage (one month before the harvest of the crop) itself, taking the advantage of the proximity to the city, where good market existed for green chickpea. People outside the village took the responsibility of harvesting the crop and helping the village farmers to overcome the labor problem.

## Difference in land utilization between small and large landholders

L arge farms underutilized the total Iand area that was at their disposal in comparison to small farms. This relative underutilization of land may have occurred because of either less irrigation availability or unwillingness to invest a high quantum of resources owing to the risk-aversion mentality. The data showed how irrigation and other inputs such as fertilizers, pesticide and FYM, decreased with increasing land size in K othapally, with labor unavailability as one of the main constraints. These were the technical reasons for land underutilization by large landholders, but there were other more complex and subtle social reasons for why the land of the upper castes was underutilized.

Farmers belonging to upper castes often had a principal occupation other than agriculture, and large landholders sometimes held or purchased land for reasons other than its use as a productive resource. This case was highlighted in Kothapally within micro-watershed, with two large landowners both practising medicine in Hyderabad city. They do not live in K othapally village and leased out their land to agricultural workers from another village. This may be an example of the fact that many large landowners held their land as a portfolio investment, and its possession may represent a hedge against inflation or a form of consumption as distinct from productive investment. This latter point might reflect the possession of land as a source of social prestige and the political influence this prestige confers.

The social dynamics within Kothapally clearly determined in some way the inverse relationship between land size and productivity. Ellis (1988) suggests that besides partial explanations such as prestige and landholding, the variations in productivity require overall economic explanations outside the technical condition of farm production. Ellis asserts that small farmers confront a low price, or in fact no cost, for labor combined with high prices for land and capital. These differences in relative factor prices results in (1) small farmers committing more labor to production than large farmers, (2) large farmers treating land as a relative abundant resource even in land scarce economy, (3) large farmers substituting machines for labor even in the capital-scarce labor abundant economy, and (4) larger farmers being overall less socially efficient agricultural producers than small farmers.

It seems that (1) and possibly (2) are economic reasons for small farmers having greater crop productivity than larger farmers in Kothapally. H owever, (3) and (4) are open to debate. Of the five large landholders surveyed in the Kothapally sample, one had recently purchased a tractor. Such machinery would undoubtedly make agricultural operations easier and more efficient. H owever, it is unknown how many agricultural laborers would lose employment opportunities because of this. Large landholders in Kothapally have emphasized the scarcity of labor. Perhaps the use of machine would make no impact upon an already labor scarce economy except on those large landholders.

## Conclusion

In Kothapally village, more than half of the population belongs to backward communities and caste always played an important role at the education level. The village is characterized by constraints which include a low level of literacy as more than 80 percent of the children and adults have no education. G ender also played an important role for people to have some form of education. Like in the other rural parts of India, less than 10 percent of females go to school in Kothapally. The proportion of irrigated area (20\%) is very less and most of the area is rainfed. Well-documented inverse relationship between land size and productivity is present in this village. The diversity in the cropping system during the rainy and postrainy season is a risk-aversion strategy being adopted by the
farmers to face the vagaries of the monsoon, scarcity of labor and other contributing factors, which affect the yield of the crops. M ost of the crops have low productivity (less than 1 t ha ${ }^{-1}$ ). The above conditions provide an ideal setting to demonstrate that through optimum inputs and crop management practices these constraints could be solved.

# Lateri Watershed, Vidisha, Madhya Pradesh, India 

PVS Rao, AB Pande, PK Joshi, SP Wani and P Pathak

## Location

The Lateri watershed is located in the northwest corner of Vidisha district in M adhya Pradesh in central India (Figure 1). M adhya Pradesh is the largest state of the country and extends into three agro-ecological zones ( 7,8 and 9) and the catchment area of the four major rivers, ie, Yamuna, G anga, N armada and G odavari. The state is divided into six physiographic regions. The district of Vidisha is located in the V indhya Plateau Zone. The Lateri block is considered the most underdeveloped area within the district of Vidisha, with very limited irrigation and no major or medium-scale industry. The average rainfall is 1100 mm . The soils of the area are predominantly medium black and to some extent red soils. A griculture is the main occupation in the black soil area, but employment is available only seasonally because of less crop intensity owing to less irrigation intensity. Twenty percent of the population from Lateri block migrates seasonally. The postrainy season (rabi) is the main cropping season when about 35,000 ha are sown while only about 10,000 ha is sown during the rainy season (kharif). D ouble cropping is undertaken on only 3750 ha (Rangnekar 1999).

The M illi watershed in the Lateri block is spread over 10,000 ha, which is located in the core soybean production zone. It receives about 1100 mm rainfall, mainly duringJ une to September. The landscape is extensively degraded because of sheet and gully erosion. A 100 ha sub-watershed is delineated for intensive soil loss and runoff monitoring on an operational-scale.

## Methodology

Primary data was collected from 102 households of 7 villages and it was analyzed. The data was collected using an interview schedule (A ppendix 2), which was filled by trained investigators through regional interviews. The schedule for data collection was prepared by the scientists of SocioEconomics and Policy Program, ICRISAT. The questionnaire followed is given in Appendix 2. The sample of the study is presented in the following sections.

Figure 1. M illi Watershed and micro-watershed in the M illi watershed.

## Farmer classification

O ut of the total 102 households, 56 percent were small landholders (landholding less than 2.5 ha), 30 percent were medium landholders (landholding of 2.5 to 10 ha ) and 15 percent were large landholders (10-30 ha). O ut of the small, medium and large landholders, more than 40 percent from each group were holding lands in the bottom parts of the toposequence and the rest hold land in the middle and top parts of the toposequence (Table 1).

Table 1. N umber of farmers in each toposequence.

| Toposequence <br> position | Small farmers <br> $(0-2.5 \mathrm{ha})$ | M edium farmers <br> $(>2.5-10 \mathrm{ha})$ | Large farmers <br> $(>10-30 \mathrm{ha})$ |
| :---: | :---: | :---: | :---: |
| Top | $17(30)^{*}$ | $7(23)$ | $2(13)$ |
| Middle | $14(25)$ | $10(33)$ | $3(20)$ |
| Bottom | $26(46)$ | $13(43)$ | $10(67)$ |
| Total | 57 | 30 | 15 |

* Values in parenthesis indicate percentages.

## Education levels

About 60 percent of the small landholders were uneducated, only 24 percent attended primary school and 15 percent attended the secondary and high schools. Of the medium landholders, 53 percent were uneducated, only 30 percent had been to primary school and 16 percent to secondary and high schools. Of the large landholders, only 20 percent were not educated, 46 percent attended primary school and around 33 percent attended the secondary and high schools.

The data in Table 2 reviews a relationship between landholding size and level of education in this watershed. It can be stated that, with the increase in landholdings, the education levels improved in these villages. The average number of persons in the family with zero, pre-school, elementary, secondary school and college level of education in the watershed were $3.26,1.92,0.5,0.23$ and 0.15 , respectively.

## Livelihood source

M ain source of the livelihoods in the watershed were from agriculture and related activities. M ain source of the income for 93 percent of small, medium and large landholders was agriculture. O nly 5 percent were agricultural laborers and 2 percent were in government services (Table 3).

The average size of the household was 9.37 persons out of which 5.25 are males and 4.12 were females. O ut of 102 households, half of the households had a family size less than the average. A bout

$\mathrm{a}=$ Agriculture; $\mathrm{b}=$ Agricultural laborer; $\mathrm{c}=\mathrm{G}$ overnment service
$10 \%$ of the households were just around the average, while the remaining $40 \%$ had family sizes more than the average. The average age of the household head was about 44 years. The family size of the landless laborers was much smaller at 5.5 persons per household. O ne hypothesis is that because the income and asset levels are lower, these households reduce the size of the family. The availability of labor was seasonal and a greater family size would require them to migrate. A recent study (Vadivelu et al. 2001) reveals that in most of the cases people with some landholdings enter into share cropping contracts and these people 'crowd-out' the landless share croppers from the share cropping market. It seems that small landholders have a better knowledge of agricultural operations and are in a better position to pay back loan borrowed from the landlord (through growing wheat than the landless share cropper from his own land).

## Landholdings and land use

The surveyed households in this watershed primarily relied on agriculture for their livelihoods. Some $97 \%$ of the households ranked agriculture as their primary occupation. The majority of the farmers did not have any secondary source of income. Farmers' landholdings included wetlands (irrigated) and drylands (non-irrigated), distributed across different topographic locations in the watershed. The correct responses indicated that some $83 \%$ of the land was located in middle toposequence, while the remaining $17 \%$ was almost equally distributed along the bottom and top of a toposequence in the watershed. The results from $47 \%$ valid responses indicated that the soil depth ranged between 0.5 m to about 4 m on some lands. Few of the farms (about 11\%) indicated soil depths less than 1 m of the valid response, $73 \%$ indicated an average soil depth on the farm ranging between 2 to 3 m .

The average total owned farm size (including cultivated, fallow and leased out and share cropped land) in the area was 5.04 ha, which amounted to 0.83 ha per capita. The average own cultivated land was about 4.794 ha, of which the average irrigated cultivated land was 0.855 ha ( $18 \%$ ) and dryland was 3.938 ha ( $82 \%$ ), indicating a per capita ownership of 0.14 ha and 0.64 ha, respectively.

The total land cultivated in rabi and kharif by the small, medium and large landholders is shown on a toposequence in Table 4. Of the total 84.5 ha land for smallholders, 23 ha were located at the top of the watershed, 20 ha in the middle and 42 ha in the bottom part. For the medium landholders, out of total 150 ha land, 3 ha were located at the top, 44 ha in the middle and 71 ha in the bottom part of the watershed. A mong the large landholders, 26 ha were at the top, 41 ha in the middle and 186 ha at the bottom of the watershed (Table 4). For all the categories, cultivated land was more in the rabi season than in the kharif season.

## Soils

The Lalatora watershed in particular was spread on the D eccan Trap basalt where the parent material is mainly alluvial. M ajority of the land area consisted of black or black/alluvial type of soils for all the landholder categories (Table 5) with fine type of soil texture (Table 6). The physiography of the area was very gently sloping land where certain pockets towards the north of the area were highly gullied creating a certain amount of relief, which might create further problems of management. Totally, five soils series were identified. These were Vertisols characterized by grey, very deep, dark grayish brown to olive brown with a clayey surface horizon and cal careous B horizon. The predominant clay mineral was montmoillonite. These soils have greater micropore volume because of high amount of very fine clay present in the soil (N BSS\&LU P 2000).

## Rainfall

Table 7 reflects the variation in the amount of rainfall over an 8-year period (ranging from 803 mm to 1136 mm per year). The variation during the sowing period was also high (ranging from 276 mm to 630 mm ). The major irrigation sources for all the category farmers were pond and river (Table 8).

## Crop production and cropping pattern

In this area, crops grown as intercrops on the same field include wheat and chickpea during rabi, and soybean and maize during the rainy season. Wheat and chickpea were also sown as sole crops. Other crops like paddy and lentils were grown as sole crops to a small extent. In kharif season, farmers grew soybean (43\% of respondents) while very few farmers grew maize and sorghum (less than $2 \%$ of respondents). In therabi season, wheat was the most frequently occurring crop in the area, followed by chickpea. A bout $89 \%$ and $86 \%$ of the sample farmers reported growing wheat and chickpea, mainly as sole crops in the rabi season. The other relatively less important crops were paddy grown by about 10\%, and lentil grown by about $7 \%$ of the farmers. All the postrainy season crops seemed to get some supplementary irrigation, while fertilizer was used on wheat, chickpea and lentils.

The major crop grown in rainy season was soybean over different parts of the toposequence (Table 9). Sorghum in about 2 ha was grown in the bottom part of the toposequence by the large landholders.

In the postrainy season, wheat and chickpea were the major crops grown by small, medium and large landholders (Table 10). Wheat was grown in about 38 ha in the top, in 77.5 ha in the middle

- N ot cropped.
and 127.6 ha in the bottom parts of the toposequence. C hickpea was grown in about 34 ha in the top, 40 ha in the middle and 113 ha in the bottom parts of the toposequence. Paddy was also grown at the top and middle parts of the toposequence in about 12 ha and 5 ha of land, respectively, whereas in the bottom part of the toposequence, large landholders used about 25 ha for paddy cultivation (Table 10).

The other major rainy season crops were sorghum and maize. Vegetables and spices such as coriander and ginger were grown by progressive farmers with good resources.

## Fertilizer input

Use of inorganic fertilizers in this area was only 75\%. Adoption of fertilizers seemed to be spread over a long time. Few farmers started using it in the eighties and many more adopted it in the nineties. Few farmers al so indicated first use around the time of the survey (1999). Those who chose to use fertilizers seemed to have continued the use. M ore work needs to be done to investigate the major constraints that prohibit a quarter of farmers in the area from using fertilizers. Despite the limited use of inorganic fertilizers, only $60 \%$ of the sample farmers indicated using FYM. N one, however, indicated using other sources such as green manures and crop residues to replenish soil nutrients. This perhaps indicates a high level of soil nutrient depletion in this watershed, as the addition of external inputs to restore soil fertility and nutrients removed with the harvest and soil erosion seems to be limited.

The fertilizer usage was more by the small landholders followed by medium landholders and large landholders. Small farmers with the fields at the bottom of a toposequence use about 318 kg DAP $\mathrm{ha}^{-1}, 300 \mathrm{~kg}$ urea ha- ${ }^{-1}, 198 \mathrm{kgFYM}$ ha ${ }^{-1}$ and 75 kg G rowmore fertilizer ha ${ }^{1}$. M edium farmers use about 432 kg DAP ha ${ }^{1}, 435 \mathrm{~kg}$ U rea ha ${ }^{-1}, 197 \mathrm{kgFYM} \mathrm{ha}{ }^{-1}, 26 \mathrm{~kg} \mathrm{G}$ rowmore fertilizer ha ${ }^{-1}$, and 23 kg super phosphate ha ${ }^{-1}$ (Table 11). L arge farmers having fields at the bottom of a toposequence used more quantity of fertilizers than that of those having fields at the middle and top of a toposequence.

## Livestock ownership

The major types of livestock in the areas included cattle, buffaloes, goats, sheep and poultry. About $86 \%$ of the respondents owned some livestock in addition to crop production activities. The average ownership of different types of animals per household were bullocks - 2, milking cows - 1.5, young

Table 11. Average Fertilizer Input (Total $\mathrm{kg} \mathrm{ha}^{-1}$ ).

| Total | 658 | 632 | 483 | 115 | 33 | 432 | 435 | 197 | 26 | 23 | 226 | 215 | 11 | 28 | 25 |

1. DAP; 2. U rea; 3. FYM ; 4. Growmore; 5. Super phosphate.
cattles - 2.5, he buffaloes - 1.5, she buffaloes - 3 , young buffaloes - 2 , goats - 5 and poultry - 3 . In Lalatora, cows were the most popular stock in about $60 \%$ of the households, followed by bullocks ( $55 \%$ ) and she buffal oes ( $43 \%$ ). O nly about $5 \%$ of the households maintained goats while none raised any sheep. The average value of livestock wealth was Rs. 22,000 per household.
The livestock (bullocks, cows, calves, buffaloes, goats, hen) ownership details are given in Table 12. The large landholders owned most of the livestock (bullocks, calves and hen) in the village. O ut of the three zones in the toposequence, the large landholders of the bottom zone had most livestock compared to the medium and top parts of the toposequence (Table 12).

## Farm implements ownership

Farmers in the watershed possessed other assets and implements (such as tractors, bicycles, plows, seed drills and bullock carts) which were mainly used in the process of crop and livestock production (Table 13). The average farm equipment and related wealth for sample households was Rs 49,873. Of this, some $50 \%$ of the households possessed assets worth less than Rs 10,000. A bout 30\% owned assets worth between Rs 10,000 and 30,000. The holding structure of important assets showed that $16 \%$ of the households owned a tractor and about 6\% owned a thresher. M ore than $58 \%$ of the households owned a seed drill, but only less than 1\% owned sprayers. A large number of farmers owned wooden plows and bullock carts.

In this village, the small landholders followed by medium and large landholders owned most of the farm implements. O ut of the small landholders, the landholders of the bottom zone owned more farm implements than that of the farmers of top and medium zones. The same trend was observed for medium and large landholders across the toposequence.

## Crop Productivities

## Crop productivity within zones and land sizes

The productivity for each crop within top, medium and bottom zones of the toposequence and small, medium and large landholders during kharif and rabi seasons has been tabulated in Tables 14 and 15, respectively.

## Kharif season

## Top zone

Small farmers: The productivity of soybean ( $0.54 \mathrm{t} \mathrm{ha}{ }^{-1}$ of grain and $0.57 \mathrm{t} \mathrm{ha}{ }^{-1}$ of fodder) was higher than that of sorghum ( $0.16 \mathrm{t} \mathrm{ha}{ }^{-1}$ of grain and $0.16 \mathrm{t} \mathrm{ha}{ }^{-1}$ of fodder).

M edium farmers: Soybean productivity of the medium farmers ( $0.16 \mathrm{tha}{ }^{-1}$ of grain and $0.12 \mathrm{t} \mathrm{ha}-{ }^{-1}$ of fodder) was nearly one-fourth of the productivity of small farmers.

L arge farmers: Large farmers achieved the highest yield of soybean (grain $0.89 \mathrm{t} \mathrm{ha}^{-1}$ and fodder 0.89 $\mathrm{t} \mathrm{ha}^{-1}$ ) followed by small and medium farmers.

## Middle zone

Among the farmers' groups in this zone, the productivity of the small farmers (grain 1.2 t ha ${ }^{-1}$ and fodder $1.04 \mathrm{t} \mathrm{ha}{ }^{-1}$ ) was higher than that of the medium and small farmers.

## Bottom zone

In this zone of the toposequence, large farmers obtained highest yield for soybean crop ( $0.9 \mathrm{t} \mathrm{ha}{ }^{-1}$ of grain and 0.72 t ha- ${ }^{-1}$ of fodder) when compared to medium and small farmers. Similarly, in the case of sorghum crop, the productivity of large farmers was greater than that of the medium farmers.

## Rabi season

## Top zone

In this zone of the toposequence, during rabi season, grain and fodder yields of wheat and chickpea crops were more for large farmers followed by small and medium farmers. The yields of large farmers were two-fold higher than that of medium farmers. In the case of rice crop, more grain yield (1.7 $t ~ h a^{-1}$ ) was observed for small farmers followed by large farmers ( 0.63 t ha- ${ }^{-1}$ ) and medium farmers ( 0.25 t ha ${ }^{-1}$ ). Lentil crop was grown by the large farmers only. Y ields were $0.4 \mathrm{tha}{ }^{-1}$ of grain 0.4 t ha $\mathrm{a}^{1}$ of fodder.

## Bottom zone

In this zone, the highest grain ( $1.53 \mathrm{t} \mathrm{ha}{ }^{-1}$ ) and fodder ( $1.18 \mathrm{t} \mathrm{ha}{ }^{-1}$ ) yields of wheat crop were observed for large farmers followed by small and medium farmers. In the case of chickpea, more grain yield ( $0.84 \mathrm{t} \mathrm{ha}{ }^{-1}$ ) was observed for small farmers when compared with large and medium landholders. Similarly, rice productivity of the small landholders was 20 folds more compared to large farmers. In this zone, oilseed was grown by medium farmers only.

## Crop productivity in Lateri watershed

In the kharif season, in all toposequences and land sizes, the highest (8 folds) yields (grain and fodder) of the soybean crop was observed for small farmers in the middle zone and the lowest of the soybean was recorded for medium farmers in the top zone of the toposequence.

In the rabi season, in the case of wheat, the highest (4 folds) yields of grain and fodder were observed for large farmers in the bottom zone whereas the lowest yields were recorded in the middle zone for small landholders. In the case of chickpea, during rabi season, the highest grain yield ( $0.95 \mathrm{t} \mathrm{ha}{ }^{-1}$ ) was recorded for medium farmers in the top zone. In the case of paddy crop, during rabi season, in the middle zone of the toposequence, medium farmers recorded the highest ( 40 folds) grain yields and the lowest grain yield was noted among large landholders in the bottom zone.

When we look at the average yields, wheat and chickpea grown as sole crops had higher yields than the intercrops. As sole stands, rabi season wheat yields were about $1.2 \mathrm{t} \mathrm{ha}{ }^{-1}$, while chickpea yields
were about 0.93 t ha- ${ }^{-1}$. In the rainy season, the average soybean yield from farmers' fields was about $758 \mathrm{~kg} \mathrm{ha}^{1}$, whereas paddy provided about $600 \mathrm{~kg} \mathrm{ha}^{-1}$.

## Cost of cultivation of soybean

- Land preparation cost - The cost of hiring a tractor is Rs $200 \mathrm{~h}^{-1}$.
- Seed cost - Rs $12 \mathrm{~kg}^{-1}$.
- Diammonium phosphate (DAP) - Rs $10 \mathrm{~kg}^{1}$.
- Single superphosphate - Rs $2.70 \mathrm{~kg}^{1}$.
- Average wage rates (per day) prevalent in the village:
- Sowing - Rs 40.
- Weeding - Rs 40 to Rs 50.
- H arvesting - Rs 50 (up to Rs. 75 in peak demand)
- The imputed labor costs of the landlord (share cropper is not computed in calculating the costs).
- The cost of threshing is Rs 3 to 5 for 100 kg of threshed soybean.

ICRISAT provided technical support through the NGO during the first year and recommended best bet option treatment to trial farmers. The best bet option for soybean includes;

Thiram:bavistin - 1:2 ratio. Thiram and bavistin seed treatment (at $3 \mathrm{gkg}^{1}$ seed) helps in healthy crop stand.

- Rhizobium - $1.25 \mathrm{~kg} \mathrm{ha}^{-1}$.
- Phosphate solubilizing bacteria - $1.25 \mathrm{~kg} \mathrm{ha}^{-1}$.
- M urriate of potash - $50 \mathrm{~kg} \mathrm{ha}^{-1}$.
- U rea-50 $\mathrm{kg} \mathrm{ha}^{-1}$.
- DAP - $125 \mathrm{~kg} \mathrm{ha}^{-1}$.

## Relationship between soil, rainfall and cropping pattern

The soils had higher clay content characterized by greater water holding capacity and there was poor drainage with high probability of waterlogging and with an average rainfall of 970 mm . Higher rainfall intensity caused greater runoff which caused soil erosion. The problem therefore in the rainy season was poor drainage and waterlogging/runoff which lead to loss of fertile top soil.

Farmers preferred to grow the rainy season crop soybean in irrigable land as they could not take care of any risks of variation in rainfall during the crop cycle, and also the delayed harvest of soybean does not affect the growth of the postrainy season crop, chickpea/wheat. In the case of dryland plots, farmers preferred to leave land fallow. Farmers real ized that sequential cropping was risky and indeed a study by Pandey (1986) found that in only about 9 out of 29 years, the residual moisture was sufficient for sequential cropping. The studies of Rosenweig and Binswanger (1993) in villages over 10 year period found that the risk-coping mechanisms (post-ante consumption smoothing mechanism are stronger) in wealthier families are better and they generally tend to take higher risk. Therefore one hypotheses that farmers with larger irrigable land are better-off farmers who can take the risks.

The average yield of all the crops except soybean was less in Lateri block than in M adhya Pradesh. The most important constraint of waterlogging in the rainy season required adequate drainage systems, $81.24 \%$ of the respondents categorized the adoption as 'partial', which, however, is hypothesized to be an over-estimation of the treatment undertaken. A recent study has found that the problem is a strong constraint and the drainage is unsatisfactory to tackle the enormous nature
of the problem (Vadivelu et al. 2001) for estimates on the co-variation in output across farms and the losses suffered because of waterlogging during the 1999 rainy season. M ost of the constraints listed for non-adoption were because of the lack of technical knowledge or the expensive nature of the perceived higher cost, which the farmer was not willing to invest. This calls for a properly designed treatment program with a reasonable contribution from the farmers to tackle the problem. C ollective action to tackle the waterlogging problem demands cooperation (human and financial).

## Summary and Conclusion

The major constraint in the watershed area is in terms of low cropping intensity as the majority of the land is left fallow during the rainy season. Waterlogging and soil erosion (top and middle zone) are the major constraints faced. The lack of initiative by the farmers is because of their perceived higher cost in undertaking these investments and they expect the government to take a lead role. The yields except for soybean in general are less than 1 t ha- ${ }^{-1}$. H owever, there is huge variation in the yields over years. The education level is poor and the women worse off as a H indu version of the 'purdah' system is followed. The infrastructural facilities in terms of electricity, roads and telecommunications are in a poor condition.

# Ringnodia Watershed, Indore, Madhya Pradesh, India 

GP Saraf, RA Sharma, OP Verma and YS Chauhan

## Location

The village Ringnodia is situated 22 km to the north of Indore city in M adhya Pradesh ( $22^{\circ} 43^{\prime} \mathrm{N}$ and $73^{\circ} 54^{\prime} \mathrm{E}$ ) on the Indore-U jjain State Highway No. 27 at an altitude of about 600 m from the mean sea level and comes under Sanwer Tehsil in Indore district.

## Methodology

The survey was undertaken in the treated area. Of the total 69 farm households, 64 were considered for the study. O nly households with land were included in the survey. Data were collected using an interview schedule (Appendix 2) and the data pertains to the crop information for the period M ay 1999 to A pril 2000.

Table 1 provides information on landholdings and cropping intensity. Majority of the small and medium landholders had land as shared in whereas most of the large landholders either had land as leased out or shared out. Details of croping systems in the farmers' fields during 1999-2000 are depicted in Figure 1.

## Table 1. Landholding information and cropping intensity.

| SI.No | Size group | Leased- <br> in land (\% of land holding) | Leased out land (\% of land holding) | Share cropped in land (\% of land holding) | Share cropped out land (\% of land holding) | Current fallow (\% of land holding) | Permanent fallow (\% of land holding) | Cropping intensity |

Figure 1. C ropping systems at Ringnodia watershed.

In the treated area, the small and marginal size farms had $41 \%$ sandy soil, $21 \%$ loamy soil and $38 \%$ clayey soil texture. The large farmers had the maximum, $60 \%$ of clayey soil in their possession with $31 \%$ loamy soil and only $9 \%$ of the land was of sandy texture in nature. The small and marginal farmers have the larger percentage of Alluvial soil (21\%), followed by medium farmers (18\%) and large farmers (17\%) (Table 2).

Table 2. Soil characteristics of the farm holdings of treated farms in Ringnodia micro-watershed.

|  |  | Soil texture(\%) |  |  | Soil type (\%) |  |  | Topography (\%) |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| SI.No | Size group | Sand | Loam | Clay | Alluvial | Red | Black | $\begin{aligned} & \text { Up } \\ & \text { land } \end{aligned}$ | Mid land | $\begin{aligned} & \text { Low } \\ & \text { land } \end{aligned}$ |
| 1 | Small and marginal (0.1 to 2.0 ha ) farms | 41 | 21 | 38 | 21 | 30 | 49 | 32 | 40 | 28 |
| 2 | M edium (2.1 to 4.0 ha ) farms | 22 | 21 | 57 | 18 | 19 | 63 | 21 | 25 | 54 |
| 3 | L arge <br> (above 4.1 ha ) farms | 9 | 31 | 60 | 17 | 18 | 65 | 15 | 34 | 51 |

The small and marginal farmers had most of their land in the midland area (40\%) and upland (32\%) with only $28 \%$ of the land in relatively more fertile low land area. In contrast, the medium (54\%) and large farmers (51\%) had most of the landholding in the low lying areas (Table 2).

The small and marginal farmers had only $19 \%$ of their land irrigated compared to $25 \%$ among medium landholders and $50 \%$ among large farmers. The major source of irrigation was through tubewells. While none of the small and marginal farmers had more than one tubewell, $8 \%$ of the medium and $25 \%$ of the large farmers possessed more than one tubewell (Table 3).

## Crop Disposition

## Small and marginal farmers

About $73 \%$ of the soybean crop was sold with $14 \%$ kept as seeds for future sowing, and about $12 \%$ was used as repayment in kind for the loans. The wheat crop was largely used for self consumption (52\%), $20 \%$ of the produce was stored and $4 \%$ was used for loan repayment in kind, $3 \%$ was used as wage payment for the harvesting and threshing operations. The gram crop was sold to the extent of $60 \%$ and $18 \%$ was held for storage and only $8 \%$ was consumed. Potato crop $92 \%$ was marketed with only $8 \%$ being used for self-consumption (Table 4).

## Medium farmers

Eighty percent of the soybean crop was sold to local middlemen. In harvesting and threshing operations, $3 \%$ of the total production was paid as wages in kind and $14 \%$ was stored. $53 \%$ of the wheat was sold, $15 \%$ of it was stored and the rest used for family consumption. In the case of chickpea, $35 \%$ of the crop was sold, $20 \%$ was stored and $43 \%$ was consumed by the family. In the case of potato, $97 \%$ of the crop was sold and the rest was used for self-consumption.
Table 3. Imigation status (\% of cultivated land) of treated farmers of Ringnodia miaro-watershed.

## Large farmers

Eighty percent of the soybean crop was sold with $16 \%$ stored as seeds and the rest was used as kind payment for wages to labor engaged for threshing. In this group, a large proportion, $70 \%$ of the wheat was sold and about $26 \%$ was stored and only $0.5 \%$ was consumed by the family and about $1 \%$ was either fed to milch animals or eaten away by rats. In the case of potato, $97 \%$ of the crop was sold, $15 \%$ of it was used as wage payment in kind and only $0.5 \%$ was used for self-consumption.

The major cause of the low yield was due to the adverse weather conditions and low rainfall. The poor resource base was also an important contributing factor (Table 5). H ence, the cropping intensity was low and most of the agricultural laborers were unable to get year-round employment.

Table 5. Yield and market price for the major crops during 1999-2000.

| SI. No. | Crop | M arket rate <br> (Rs. per quintal) | Yield <br> $\mathrm{kg} \mathrm{ha}^{-1}$ |
| :--- | :--- | :---: | ---: |
| 1 | Soybean | $950-1050$ | 900 |
| 2 | Wheat | $600-950$ | 2200 |
| 3 | Chickpea | $950-1200$ | 750 |
| 4 | Potato | $200-275$ | 20000 |

## Technology Adoption

## Fertilizer and pesticide adoption

The application of farmyard manure (FYM) and the use of pesticides were low in all groups (Table 6a).

## Table 6a. Fertilizer and pesticide usage by different groups of farmer.

## Soil \& Water conservation practices

## Small farmers

Keyline cultivation was not implemented/adopted by any of the farmers, because of the lack of knowledge about the practice. Leveling and smoothing was practised in at least one field by 79 small farmers, $12 \%$ reported that it was not technically suitable in their location, $8 \%$ reported that it was costly. D ug out ponds were not in use, with $19 \%$ reporting lack of knowledge and $92 \%$ reported that it was not technically suitable. The construction of ponds was expressed as a costly option by $92 \%$ of the respondents, $87 \%$ of them said that there would not be any cooperation among the farmers for such a venture. Sixty-two percent of the respondents reported lack of know ledge on the construction of waste weirs, $42 \%$ considered it to be not technically suitable, $62 \%$ reported that it was a costly option. D eep ploughing was considered as unsuitable for their locations by $42 \%$ of the respondents and $92 \%$ of them considered it costly.

## Medium farmers

Keyline cultivation was not known and considered inconvenient by 92\% of the respondents; 16\% found it technically not suitable to their specific locations; $25 \%$ reported that it was a costly option. Leveling and smoothing was considered inconvenient by $50 \%$ of the respondents, while $25 \%$ of them considered it too costly. Dug out farm ponds were considered technically suitable by $92 \%$ of the respondents and all of them considered it to be costly. There was no knowledge on waste water weirs by $42 \%$ of the respondents, $25 \%$ reported that it was not technically feasible and $75 \%$ of them considered it costly and $92 \%$ of them said that the neighboring farmers would not agree to it.

## Large farmers

There was no knowledge of keyline cultivation by $75 \%$ of the farmers and $25 \%$ were of the view that it was not technically suitable. Leveling and smoothing was considered technically unsuitable by $25 \%$ of the respondents; $25 \%$ of them considered it costly while $25 \%$ considered it inconvenient. Dug out ponds considered were technically unfeasible by all the respondents, $75 \%$ of them reported that it was costly. All the farmers stated that there would be no cooperation from the neighboring farmers for such a venture. Waste water weirs were considered costly by $50 \%$ of the respondents; $25 \%$ reported lack of knowledge and an equal proportion considered it technically unfeasible. D eep ploughing was practised by $25 \%$ of the farmers; $50 \%$ of them considered it costly.

## Crop yields and benefit-cost ratios

## Soybean

Seventy-three percent of the farmers grew the Soybean JS 335 variety, 18\% grew the Punjab1 variety and 9 percent grew the short duration Samrat variety. Small and marginal farmers incurred Rs 5677 $\mathrm{ha}^{-1}$ towards cost of cultivation with a yield of $850 \mathrm{~kg} \mathrm{ha}^{1}$. M edium farmers and large farmers incurred Rs 6683 ha $^{-1}$ and Rs 7074 ha $^{-1}$ towards cost of cultivation with yields of $920 \mathrm{~kg} \mathrm{ha}^{-1}$ and 956 kg ha- ${ }^{-1}$, respectively(Table 6b).

## Wheat

Small farmers incurred Rs 8291 ha $^{-1}$ towards cost of cultivation with a yield of $1680 \mathrm{~kg} \mathrm{ha}^{-1}$. M edium farmers and large farmers incurred Rs 10,098 and Rs 10,048 with yields of $2510 \mathrm{~kg} \mathrm{ha}^{-1}$ and 2470 kg ha ${ }^{-1}$, respectively (Table 6c).

Table 6b. Soybean yield and B-C ratio.

## Constraints to production practices

## Technology - constraints

Low germination of the seeds was reported as a constraint by more than $25 \%$ of the farmers. Lack of local availability of the improved varieties of seeds was reported as a constraint by more than $40 \%$ of the farmers. These problems reflected the prevalence of weak systems of local seed storage by the farmers and lack of supply in the private markets and the public seed systems (Table 7a).

Table 7a. C onstraints to production practices pertaining to technology: seed and seed treatment.

| Sl. no. | Particulars | Small (48) | M edium (12) | Large (4) |
| :--- | :--- | :---: | :---: | :---: |
| 1 | Low germination | 33 | 33 | 25 |
| 2 | Low purity | 19 | 18 | 25 |
| 3 | Uneven germination because of uncontrolled depth | 19 | 25 | 25 |
| 4 | Late sowing because of unavailability of seed in time | 10 | 17 | 25 |
| 5 | Complete immunity not ensured by seed treatment | 12 | 8 | 25 |
| 6 | Lack of local supply of improved seed | 39 | 42 | 50 |
| 7 | Lack of knowledge about sowing methods | 10 | 8 | Nil |
| 8 | U navailability of recommended variety | 39 | 42 | 75 |

## Water management

M ore than $75 \%$ of the respondents lacked any irrigation facility, with more than $50 \%$ holding the opinion that alternative irrigation was not possible. All the respondents reported that the declining water table was a major constraint (Table 7b).

Table 7b. C onstraints to production practices pertaining to water management.

| SI. no. | Particulars | Small (48) | M edium (12) | Large (4) |
| :--- | :--- | :---: | :---: | :---: |
| 1 | Lack of irrigation | 75 | 75 | 100 |
| 2 | Undulatingland | 19 | 8 | Nil |
| 3 | Lack of knowledge about irrigation methods and time | 12 | 17 | 25 |
| 4 | Alternative irrigation is not possible | 75 | 50 | 50 |
| 5 | D efective land shaping | 39 | 25 | 25 |
| 6 | Stagnation of water in the field because of inadequate |  |  |  |
|  | drainage system | 10 | 8 | Nil |
| 7 | Declining water table | 100 | 100 | 100 |

## Fertilizer and manure management

According to most of the respondents, high application rates of fertilizers was resulting in increased diseases and pest attack. A possible reason for higher application of fertilizers was the lack of availability of FYM, which was reported as a constraint by more than $80 \%$ of the farmers (Table 7c).

Table 7c. C onstraints to production practices pertaining to fertilizer and manure management.

| SI. no. | Particulars | Small (48) | M edium (12) | Large (4) |
| :--- | :--- | :---: | :---: | :---: |
| 1 | Judicious balancing with recommended |  |  |  |
|  | phosphatic and potassic fertilizer is not |  |  |  |
|  | necessary for the respective soils |  |  |  |
| 2 | High doses of fertilizer spoils the soils |  |  |  |
| 3 | Induction of more diseases and pests through | 83 | 8 | 25 |
|  | application of fertilizers |  | 75 | 75 |
| 4 | Fertilizers application is more expensive | 62 | 42 | 50 |
| 5 | Loss of fertilizer through leaching and runoff | 92 | 58 | 50 |
| 6 | Poor soil conditions | 42 | 42 | 25 |
| 7 | Lack of timely supply | 44 | 17 | 25 |
| 8 | Non availability of FYM | 44 | 50 | 25 |
| 9 | Poor quality of FYM | 81 | 92 | 75 |
| 10 | Lack of timely supply of FYM | 50 | 42 | 50 |
| 11 | Poor fertilizer supply | 44 | 50 | 50 |
| 12 | FYM is not necessary | 31 | 17 | 25 |
|  |  | 12 | 8 | 25 |

## Weed control

Chemical application was not found as effective as hand weeding by more than $75 \%$ of the respondents, who also reported that their knowledge on weedicides was inadequate. However, weedicide was used as hand weeding was considered labor consuming and expensive, more in the case of medium sized farmers (42\%) (Table 7d).

## Disease and pest control

M ost of the respondents felt that spraying was not effective and lack of knowledge and availability of plant protection material was a major constraint, especially according to small farmers. M ore than $65 \%$ of the respondentsfeel that the pests and diseases are not under control and chemical application was considered as toxic to animals and humans (Table 7e).

Table 7d. C onstraints to production practices pertaining to weed control (\% of sample per group).

| SI. no. | Particulars | Small (48) | M edium (12) | Large (4) |
| :--- | :--- | :---: | :---: | :---: |
| 1 | Chemical application not effective as hand weeding | 81 | 75 | 75 |
| 2 | Difficulty weeding in irrigated field | 27 | 25 | 25 |
| 3 | Weedicide cause toxicity to crop | 27 | 17 | Nil |
| 4 | H and weeding time and labor consuming thus expensive | 33 | 42 | 25 |
| 5 | High cost of weedicides | 81 | 33 | 50 |
| 6 | Inadequate knowledge of weedicide use | 77 | 75 | 75 |

Table 7e. C onstraints to production practices pertaining to disease and pest control (\% of sample in each group).

| SI. no. | Particulars | Small (48) | M edium (12) | Large (4) |
| :--- | :--- | :---: | :---: | :---: |
| 1 | Spraying is not effective | 19 | 17 | 25 |
| 2 | M ost the disease/pest are not under control | 67 | 83 | 75 |
| 3 | Lack of supply of plant protection material | 73 | 58 | 50 |
| 4 | Capital insufficient | 81 | 67 | 50 |
| 5 | Lack of knowledge about plant protection | 81 | 50 | 25 |
| 6 | Lack of local supply | 81 | 75 | 75 |
| 7 | Chemical are more toxic to animal and humans | 77 | 67 | 25 |
| 8 | No problem of disease and pests in the field | 10 | 8 | 25 |

## Credit

Credit availability was a general constraint to all the respondents. The interest rate was also high with variation from one organization to another (institutional credit market vis-à-vis local credit markets with very high rates of interest, normally around $36 \%$ ). The transactions costs in obtaining a loan and the recovery procedures were considered a major constraint in accessing institutional credit markets (Table 7f).

Table 7f. C onstraints to production practices pertaining to credit (\% of sample in each group).

| SI. no. | Particulars | Small (48) | M edium (12) | Large (4) |
| :--- | :--- | :---: | :---: | :---: |
| 1 | N ot available from one agency and in time | 100 | 100 | 100 |
| 2 | Rate of interest is high but varies from agency to agency | 81 | 75 | 75 |
| 3 | Complicated loan procedure | 81 | 75 | 50 |
| 4 | Recovery procedure is stringent | 67 | 50 | 50 |
| 5 | The various fees, charges and costs involved in running |  |  |  |
|  | credit agencies are very high | 77 | 50 | 25 |

## Marketing

Lack of bargaining power which results in lesser realization through the sale of the output was perceived by the respondents as a major problem. This was especially the perception of the small and medium sized farmers (73\% and 67\%), respectively (Table 7g).

| Table 7g. C onstraints to production practices pertaining to marketing (\% of sample in each group) |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- |
| SI. no. | Particulars | Small (48) | M edium (12) | Large (4) |
| 1 | M onopoly and forced marketing in grain market/ |  |  |  |
|  | vegetable market | 73 | 67 | 50 |
| 2 | Late and inadequate returns in market | 77 | 75 | 75 |
| 3 | M arket located at a distant place | 67 | 58 | 50 |
| 4 | High transportation charges | 77 | 50 | 25 |
| 5 | U nauthorized charges | 33 | 25 | 25 |

## Extension

The extension support from the agriculture department and the university was not found satisfactory with more than $50 \%$ of the respondents finding it 'inadequate' (Table 7h). It was felt that the local youth were not provided with the required technical information. The trainings were conducted at distant places which were perceived as a constraint.

| SI. no. | Particulars | Small (48) | M edium (12) | Large (4) |
| :---: | :---: | :---: | :---: | :---: |
| 1 | Farmers training conducted at distant place | 81 | 75 | 75 |
| 2 | Improved production techniques are not demonstrated in the field | 33 | 25 | 25 |
| 3 | Intensive contact of subject matter specialists from university and agriculture department is low | 67 | 50 | 50 |
| 4 | Key information and important technical information are not provided to village youth | 77 | 75 | 75 |

## Summary and Conclusion

The small and marginal farmers possess higher percentage of upland where generally the soil quality is poorer ( $32 \%$ ). A mong the small landholders, $81 \%$ of the land is unirrigated when compared to $75 \%$ among the medium size farmers and $50 \%$ among the larger farmers.

All the farmers are of the opinion that the groundwater level is going down (data required on the groundwater depth, depth of the water availability from sample wells, borewells).

The intensity of input application is lower in the case of smaller farmers compared to the medium and large farmers and the intensity of medium farmers is lower when compared to large farmers. The intensity of fertilizer and FYM application is high among large farmers. The yields of all the crops also reflect that the productivity is lower in the case of the farmers who had lower inputs costs. The reasons for lesser input application are risk aversion strategy, lower area under irrigation and higher proportion of land in the upland combined with higher proportion of poorer quality soil (sandy and loamy constitute $41 \%$ in the case of small and marginal farmers).

As far as adoption of SWC measures are concerned, there is no practice of keyline cultivation, waterways, dugout ponds and waste water weirs among all the farmers. The reasons for non-adoption reported by farmer are lack of knowledge, poor technical suitability and lack of cooperation among the farmers. On an average, 76\% of the farmers practice leveling and smoothing operation in at least one of their plots.

# Tad Fa Watershed, Khon Kaen Province, Northeast Thailand 

Somchai Tongpoonpol, Arun Pongkanchana, Pranee Srihaban and TJ Rego

## Introduction

Agriculture is the main occupation in Thailand and it plays an important role in the economic development of the country. Thailand is located in the tropical monsoon climate region where the amount of rainfall is high, but shortage of water occurs even in the rainy season. Only 20 percent of the total agricultural area is under irrigation. The rest constituting rainfed area has relatively lower crop yields. The rainfed area faces the problem of soil erosion and reduced soil productivity.

The northeastern part of Thailand occupies one-third of whole country. The climate of the region is drier than that of the other regions. M ost of the soils in northeast Thailand are infertile at present and liable to be further degraded. The empirical evidence shows that the yield of crops is found to decrease year by year after the conversion of the area as agricultural land because of deforestation. The infertility of the soils has been caused by improper soil management. The soils are low in fertility, have low water holding capacity (WHC), and soil erosion is a perennial problem. The interventions by ICRISAT project address these problems in the rainfed areas of northeast Thailand. The watershed area in Phu Pa M an district in K hon Kaen province has been selected as benchmark site to address the above problems and increase agricultural productivity through a sustainable manner by adopting integrated soil, water, and nutrient management (SWNM) and integrated crop management options.

## Physical resources

## Location and extent

N ortheast Thailand is situated between $14^{\circ}$ to $19^{\circ} \mathrm{N}$ latitude and $101^{\circ}$ to $106^{\circ} \mathrm{E}$ longitudes. The area is about 17 million ha (one-third of the whole country) and is spread over 19 provinces, which are K alasin, Khon Kaen, C haiyaphum, Y sothon, N akhon Phanom, Nakhon Ratchasima, Burirum, M aha Sarakham, Roi Et, L oei, Sri Sa Ket, Sakon N akon, Surin, N ong Khai, U don Thani, U bon Ratchathani, Mukdaharn, Nong Bua Lam Phu and Amnat Charoen.

The topography of northeast Thailand is generally characterized by high plateau with the ranges of Phetchabun and D ong Phayayen in the west, Phaya D ong Rak bordering Thailand with C ambodia in the south and southeast, and M ae Khong river bordering with the Democratic Republic of Laos (LAO SPPR) in the north. In the middle, the range of Pu Pan divides the watershed area into 2 basins - Sakhon $N$ akhon basin on the upper part and $M$ un watershed on the lower part (Figure 1).

D espite receiving same amount of rainfall, northeast Thailand is drier than north and central Thailand because of the shorter rainy season. Farming is the main occupation, with only 20 percent of the total agricultural area under irrigation. The productivity is low with the farmers facing problems of soil salinity and soil erosion.

## Topography

N ortheast Thailand, or the "K horat Plateau" is characterized by shallow basin (saucer-shaped basin). The plateau consists of flat-topped mountains and dissected peneplain surface with undulating features. The elevation varies from 200 meters to 1000 meters above mean sea level (msl).

Figure 1. Location of the watershed.
G eologically, the region can be divided into 6 parts.

## Western highland

This area is distinct by hilly to mountainous topography, except the area close to northeastern part which is undulating to rolling topography. It covers the province of Loei and some parts of Udon Thani, Khon Kaen, Chaiyapum and N akhon Ratchasima.

## Northern highland

This area is formed as thin strip on the northernmost region. The topography is rolling to hills underlaid by lower and middle Khorat group. It covers some part of N ongkhai province and N akhon Panom province.

## Sakhon Nakhon basin

This basin is in the north of the region where Sakhon Nakhon province is located in the middle. The basin covers the provinces of Nakhon Panom, Sakhon Nakhon, U don Thani and Nongkhai. The topography is flat to undulating underneath by evaparite-bearing salt formation. The area is approximately $43,000 \mathrm{sq} \mathrm{km}$, and the streams mainly flow to Nong H an, the biggest Iagoon in Thailand with 170 sq km size, and then flow to M aekhong river via N um Karn stream. M oreover, Songkram river originating in the north joins with M ae Lhong river flowing through the northeastern part of the plateau.

## Central highland

This area is characterized by rolling to hilly topography. The range of Phu Pan is situated in southeastern part with lower and middle Khorat group underneath. Phu Pan range is extended to M aekhong river.

## Khorat basin

The basin is located in the south of the region where Roi Et province and the north of N akhon Ratchasima province are in the middle. It also covers the province of Surin, Sri Saket, Nakhon

Ratchasima, U bon Ratchatani, Roi Et, Burirum, M ahasarakam, Chaiyapum, Yasothon, Khon K aen and Kalasin. The topography is flat or almost flat or undulating. The area is about $137,000 \mathrm{sq} \mathrm{km}$. The basin receives water from M un river which originates in the southeastward mountain and flowing from the east to the south. The watershed area is about $82,000 \mathrm{sq} \mathrm{km}$. Chi river originated in the rim of the western plateau, and flows to the middle of the basin joining the $M$ un in $U$ bon Ratchthani province of the plateau. The Chi then flows to the Maekhong in the southeast. Chi watershed is approximately 55,000 sq km.

## Southern lowland

This area is situated in the southernmost region, where Panom D ong Rak range is formed as a strip. The topography is sloped northward towards M un river and characterized by flat to undulating with some hilly topography in many areas especially the province of Surin Burirum and the southeast of Nakhon Ratchasima province. The basalt rock in tertiary area is lying underneath. From the above characterization, northeast Thailand can be described in 3 areas (ie, highland, upland and lowland).

## Climate

N ortheastern Thailand is located on the low latitude and is influenced by tropical low-rainfall climate and wet-dry monsoon or tropical Savannah climate. During November to February, the area is influenced by the northeast monsoon from the Eurasian continent resulting in a cooler and dry weather and covering the whole region. The southwest monsoon during M ay to September brings in warm and moist weather from Indian O cean. There are three seasons in a year.

## Rainy season

The rainy season starts in May or in the beginning of June and lasts into the beginning of October because of the effect of southwest monsoon. The rainfall owing to the southwest monsoon is lower than the rainfall caused by depression from the South C hina sea, because the ranges of Phetchabun in the northeast and D ong Phayayen in the west, and the ranges of San Khampaeng and Phanom Dong Rak in the south are the barriers.

## Winter season

The winter season begins in mid-O ctober and lasts into mid-February. This is caused by the northeast monsoon from China which brings a cool and dry climatic mass without vapor to the area. Thus the weather is very cool in the north and warm in the south.

## Hot season

The hot season begins in February and lasts until the end of May. It is caused by the northeast monsoon from the South C hina sea and the gulf of Thailand. Because the northeast is located far away from the gulf of Thailand, the climate is hot and very dry in the region. The summary of climatological parameters of many stations in northeast Thailand during 1988-1997 is given in Table 1.

## Rainfall

The rainfall in the northeast Thailand is about 1375 mm per year. The rainfall in the west and in the middle of the region such as C haiyapum, N akhon Ratchasima, Loei, Khon K aen and Roi Et province is

| Province | 1988 | 1989 | 1990 | 1991 | 1992 | 1993 | 1994 | 1995 | 1996 | 1997 | Average |

lower than the rainfall in the east and the north which is about $1000-1400 \mathrm{~mm}$. The rainy days are about 108. In the eastern and northern regions such as N akhon Panom, Sakhon N okhon, N ong Khai, U bon Ratchatani, U donthani and M ukdahan province, the annual rainfall is about 1500-2300 mm. There are 123 rainy days (Figure 2).

Source: Land Development department Soil and water Conservation Division
Figure 2. Rainfall distribution in the watershed.

## Temperature

The mean temperature in northeast Thailand is about $26.7^{\circ} \mathrm{C}$. H ot season starts in M arch and lasts into M ay and winter starts in N ovember and lasts into February. M aximum temperature is $27.4^{\circ} \mathrm{C}$ in N akhon Ratchasima province, and $25.7^{\circ} \mathrm{C}$ in Sakhon N akhon (Figure 3).

Bource: Lersd Development department Boil and water Cormervation Division
Figure 3. Temperature distribution in the watershed.

## Irrigated area and water resources

The water resource in the northeast is surface water. The area consists of 2 basins - K horat basin and Sakhon $N$ akhon basin. The range of Phu Pan is the barrier between these basins.

## Water resources in Sakhon Nakhon basin

The Sakhon $N$ akhon basin is made of N ongkhai, Sakhon $N$ akhon and $N$ akhon Panom province. The streams flow to the north and then to the east, finally joining the M ekong river. Song Khram is an important river. It originates in Phu Pan range and flows through the province of Sakhon Nakhon, N ongkhai and joins with the M ae K hong in N akhon Panom province. The other river is H uai Luang. It joins the Song Khram river in $N$ akhon Panom province and then flows to the $M$ aekhong. There are many more streams such as N um Pung flowing to the N ong H an in Sakhon N akhon province.

## Water resources in Khorat basin

The basin is located in the south of Phu Pan range or in the north of the provinces of Khon Kaen, Kalasin, Nakhon Ratchasima, Maha Sarakham, Roi Et, Yasothon and Ubon Ratchathani. The important rivers are Chi and M un. M un river originates in the ranges of the southeast. It flows eastwards through the provinces of $N$ akhon Ratchasima, Burirum, Surin, Sri Sa K et to the M aekhong in U bon Ratchathani province. Its tributaries are made of Lum Ta Khong, Lum Pra Pleong, Lum Plai M at, Lum Dom Yai, Lum Dom Noi etc.

C hi river originates in the ranges of the provinces of L oei, C haiyapum and K hon Kaen. There are three main tributaries joining the Chi river. They are Num Pang originating in Loei province, Num Proom originating in Chaiyapum province and $N$ um Pao or Lum Pao originating in Kalasin. These rivers join the C hi river at K oengnai and Warinchumrap district in U bon Ratchathani province, and then flows to the M aekhong in the east. Lum $\mathrm{Se}, \mathrm{H}$ uai Se Bok and Lum Num young are some tributaries of Chi river. The streams in the northeast normally have water only during some periods of the year and there is water shortage during the dry season, even in the main rivers such as Chi, M un and Song Khram. Water resources development is being promoted in approximately 4.64 million ha or about 20 percent of the agricultural land.

## Soil

The northeastern Thailand soils consists of 9 sub-orders - U sterts, Aquepts, Tropepts, U stolis, Aqualfs, U stalfs, Aquults, U stults and U dults (Figure 4). The soil is characterized by sandy or sandy loam to sandy clay loam texture with low to medium fertility. U stults is the largest one and mainly used for field crops (ADRC 1989). Aquults is less than U stults, which is flat and mainly used for paddy rice (Figure 4).

## Land use

The three kinds of forests are described below.

## Dry dipterocarp forest

Dry dipterocarp forest exists in this region both in the flat plains and in the highlands. These forests are located in the elevated area, but below 1000 meters above msl. It is characterized by sandy or lateritic soil. This area is dry with low soil productivity.

Figure 4. Soil distribution in northeastern Thailand.

## Mixed deciduous forest

The mixed deciduous forest is composed of medium-size trees. These forest types are found more in the provinces of Khon Kaen, Nong K hai and $N$ akhon Panom.

## Tropical rain forest

Large trees with high rainfall characterize the forests. M ost of the area has been deforested and a greater proportion of the remaining area is in the provinces of Loei and $N$ akhon Ratchanima.

## Physical characteristics of the watershed

The Tad Fa watershed is located within the three main watersheds, namely, subsystem of M ae Khong watershed in the northeast, Chi watershed in the east and Pasak watershed in the southwest. The biophysical and socioeconomic data were collected so as to analyze the ecological type of the watershed. The related parameters of ecoregional database comprised the rainfall, evaporation, temperature, elevation, soil and land use.

The existing data concerning the biophysical and sociological data were analyzed to present the important data in terms of watershed name, watershed code, location, latitude, longitude, area, length of main river, highest elevation, geomorphology, dam/reservoir, annual rainfall, runoff, population, province and land use, which were the main characteristics of the whole watershed as shown in Tables 2,3 and 4.

## The ecoregional data

## Rainfall

The rainfall data collected by the Department of M eteorology were selected during the year 19881997 (10 years). The average annual rainfall of the three main watersheds were analyzed based on the rainfall data within the area of those three watersheds.

## Evaporation

The evaporation data collected by the Department of M eteorology were selected during the year 1988-1997 (10 years). The average annual evaporation of the three main watersheds were anal yzed based on evaporation data within the area of those three watersheds.

- M ae Khong watershed; data were from the provinces namely Loei, Nong Khai, Sakon Nakhon, N akhon, Phanom, M ukdahan and Amnat charoen.
- C hi watershed; data were from the provinces namely U don Thani, Khon K aen, N ong Bua Lam Phu, C hayaphum, K al asin, M aha Sarakham, Yasothon, N akhon Ratchasima, Sri Sa Ket, Roi Et and U bon Ratchathani.
- Pasak watershed; data were from the provinces namely Phetchabun, Lop Buri and Saraburi (Figure 5).

## Temperature

The temperature data collected by the Department of M eteorology were selected during the year 1988-1997 (10 years). The average annual temperatures of the three main watersheds were analyzed based on temperature data within the area of those three watersheds.

- M ae Khong watershed; data were from the provinces namely Loei, Nong Khai, Sakon Nakhon, N akhon Phanom, M ukdahan and Amnat charoen.

- Pasak watershed; data were from the provinces, namely, Phectchabun, Lop Buri and Saraburi.

## Topography

The result of the analysis of landform and slope class map done by LDD is shown in the Figure 6.

## Elevation

The contour map of the Royal Thai Survey was introduced and used as the base map for analysis of the contour interval which were grouped into 5 levels ranging from 100-200 meters, 200-500 meters, 500-1000 meters, 1000-2000 meters and more than 2000 meters.

Figure 6. Topography and drainage lines map of Tad Fa micro-watershed.

## Soil

The result of the soil analysis is shown in the Figure 4.

## Land use

The result of the analysis of land use map done by LDD in 1998 is shown in Figure 7.

Figure 7. Land use map of H uay Lad Watershed.

## Criteria approach

The following criteria were chosen to analyze and group the data.

## Rainfall

The data of mean annual rainfall were grouped into 4 classes ranging 1000-1200 mm, 1201-1400 $\mathrm{mm}, 1401-1600 \mathrm{~mm}$ and more than 1600 mm (Table 5). Then, the areas of each interval were measured for their percent and area of the whole watershed (see Figure 2).

## Evaporation

The data of mean annual evaporation were grouped into 7 classes ranging as follows (Table 6):
The areas of each class were measured for their percent and area of the whole watershed as shown in Figure 5.

Table 5. Rainfall ranges.

| Rainfall (mm) | Class |
| :--- | :---: |
| $1000-1200$ | 1 |
| $1201-1400$ | 2 |
| $1401-1600$ | 3 |
| $>1600$ | 4 |

Table 6. Evaporation classes.

| Evaporation (mm.) | Class |
| :--- | :---: |
| $1400-1500$ | 1 |
| $1501-1600$ | 2 |
| $1601-1700$ | 3 |
| $1701-1800$ | 4 |
| $1801-1900$ | 5 |
| $1901-2000$ | 6 |
| $>2000$ | 7 |

## Temperature

The data of mean annual temperature were grouped into 4 classes as shown below (Table 7) and in Figure 3.

## Table 7. Temperature classes.

| Temperature | Class |
| :--- | :---: |
| $25.0-26.0$ | 1 |
| $26.1-27.0$ | 2 |
| $27.1-28.0$ | 3 |
| $28.1-29.0$ | 4 |

## Topography

The topographic maps were introduced to analyze and were subdivided into 3 levels as shown in Table 8.

Table 8. Topography classes.

| Topography | Class |
| :--- | :---: |
| Slope Complex | S |
| Up Land | $U$ |
| Low L and | L |

## Hypsographic

The analyzed mean sea level was grouped into 5 classes (Table 9) as shown in Figure 8.

## Table 9. H ypsographic classes.

| Hypsographic M SL | Class |
| :--- | :---: |
| $100-200$ | 1 |
| $200-500$ | 2 |
| $500-1000$ | 3 |
| $1000-2000$ | 4 |
| $>2000$ | 5 |

Figure 8. H yposometry map of the three watersheds: M aekhong, C hi and Pasak.

## Soil

Figure 4 shows the soil map by LDD in suborder.

## Land use

The land use maps prepared by LDD in 1998 is shown in Figure 9.

Figure 9. L and use map of Tad Fa Watershed.

## Agricultural productivity - yield gap analysis in northeast Thailand

The amount of rainfall in the region was lower than in the other regions. So agriculture was based mainly on upland crops such as cassava, sugarcane, maize, upland rice, groundnut and soybean. This study was done on sustainable agriculture and emphasized on crops, which minimized the use or the
destruction of natural resources and improved the soil quality. The following five crops were selected for this study - rice, maize, soybean, groundnut and sunflower.

## Rice

Rice is an economically important crop to the Thai society. Since 1979, the export of rice has assumed increased importance. The total area of production and productivity are given in Table 10.

Table 10. Rice production by region in 1998.

| Regions | Planted Area (rai)* | H arvested area (rai) | Production (in tons) | Yield (kg rai-1) |
| :---: | :---: | :---: | :---: | :---: |
| N ortheastern ( NE ) | 31,040,327 | 28,543,360 | 8,009,659 | 281 |
| N orthern ( N ) | 12,526,986 | 11,217,283 | 4,975,721 | 444 |
| Central Plain (C) | 9,886,193 | 9,406,367 | 4,289,886 | 456 |
| Southern (S) | 2,919,666 | 2,677,407 | 885,449 | 331 |
| * 6.25 rai $=1$ ha |  |  |  |  |

Yield in the northeastern was 50\% lower than the yield in research plots and 11\% lower than that of the whole country (Table 11). W hen considering the morphogeology of the northeast, yield in the highland and upland area was lower than that of the whole country and the yield was high in plain flat lands.

The upland rice was grown for household consumption. Farmers did not grow upland rice for trading, because the quality of seeds did not meet the requirement of the market. The yield of the upland rice was also $50 \%$ lower than that of the paddy field.

The upland rice yield in the northeast was 28\% lower than the research plots yield and about 18\% lower than the yield of the whole country (Table 12).

## Maize

In Thailand, maize is being grown for the last 40 years. During 1988-1992, Thai maize production had decreased by $7 \%$, mainly because of frequent droughts during crop season. This resulted in farmers shiftingto other drought resistance crops such as sugarcane and cassava. Out of a total production area of 8.8 million rais, 2.3 million raiswas in the northeastern part of the country (Table13). Theyield was lower than theyield in other regions.

The corn yield of the northeast was $47 \%$ lower than the yield in the research plots, $12 \%$ lower than that of the country (Table 14). Considering morphogeology, yield in highland and upland area was lower than that of the whole country, and the yield is high in the lowland.

## Soybean

In Thailand, soybean is being grown since 1936. In northern part of the country, farmers were recommended to grow soybean after rice. H owever, the seeds were imported from C hina and J apan, which were not suitable to the local conditions in Thailand. In 1960, variety improvements were undertaken and many good varieties were produced. Due to an increase in the livestock population, the requirement of soybean reached 2 million tons per year. From the total production area of 2.6 million rais, Thailand produced 0.5 million tons per year. The northeastern part of the country grew soybean in 349,613 rais (Table 15). The yield in the region was low.

Table 13. Maize production by region in 1998.

## Groundnut

G roundnut is an important crop in Thailand introduced by the Portuguese. Since 1962, the department of agriculture initiated research efforts to improve the varieties. O ut of a total area of 4.5 million rais, the groundnut area in the northeast was 228,565 rais. The yield was low at $214 \mathrm{~kg} \mathrm{rai}^{-1}$ (Table 17).

Table 17. G roundnut production by region in 1998.

| Region | Planted area <br> (rais) | Production <br> (tons) | Yield <br> $\left(\mathrm{kg} \mathrm{rai}^{-1}\right)$ |
| :--- | :---: | ---: | :---: |
| N ortheastern (NE) | 228,565 | 50,617 | 214 |
| N orthern (N) | 295,850 | 69,919 | 238 |
| Central Plain (C) | 96,881 | 24,465 | 247 |
| Southern (S) | 29,375 | 3,169 | 176 |

The groundnut yield in the northeastern region was $23 \%$ lower than that of the research plots and $7 \%$ lower than that of the rest of the country (Table 18). M orphogeologically, the yield in the highland and upland area was lower than the yield in the whole country and it was higher in the lowland areas.

| N ortheastern on highland yield (N hy) | 186 | $92(33 \%)$ | $45(19 \%)$ |
| N ortheastern on upland yield (Nuy) | 211 | $67(24 \%)$ | $20(9 \%)$ |
| N ortheastern on lowland yield (N ly) | 247 | $31(11 \%)$ | $16(7 \%)$ |

## Sunflower

Sunflower, which originated in the west of the U nited States of America was introduced into Thailand in 1973. But it was not successful because of its low yield and marketing problems. Since 1987, extension efforts were directed to introduce it as the second crop in the central plain such as Saraburi and Lob Buri. In other areas, it is grown by a few farmers and still cannot be classified as an economic crop (Table 19).

In the northeastern region, the yield is lower than the research plots yield by 6\% and $0.4 \%$ lower than that of the country as shown in Table 20.

Table 19. Sunflower production in 1993.

| Region | Planted area <br> (rais) | Production <br> (tons) | Yield <br> (kg rai-1) |
| :--- | ---: | ---: | :---: |
| N ortheastern (NE) | 63,500 | 14,980 | 235 |

## Analysis of constraints in the watershed

It was apparent that in Thailand, a few of the factors and constraints involved in agricultural productivity are nationwide. M ostly they had specific regional or provincial relevance. C onstraints on productivity could be discussed under the following headings.

- Physical constraints
- Technological constraints
- Institutional constraints
- Socioeconomic constraints

## Physical Constraints

Physical constraints had a major impact on agricultural productivity. The main physical constraints were

- Climatic, especially rainfall, relative humidity, and dry season temperatures
- Relief or topography
- D rainage and flood hazards
- Soils
- Accelerated erosion and runoff

## Climatic constraints

The major climatic constraint was the low rainfall in dry season. A less important climatic constraint was the high relative humidity in the wet season, which encourages pest and diseases in dry-land crops such as maize and sugarcane. In the dry seasons, temperatures decreased with the increase in altitude in the mountains. Temperature restricted the range of introducing tropical perennial crops that could be grown. Although at the same time, there was a possibility of introducing temperate crops. H owever, the area affected by this constraint was very limited in extent and was generally lacking in agricultural potential for reasons of topography and soil.

## Topographic constraints

The steep and uneven slopes made cultivation difficult and resulted in rapid runoff of rainfall, accompanied by sheet and gully erosion.

## Drainage and flood constraints

Flooding was the major factor resulting from intensive rainfall in the wet season causing rivers to rise and inundate large areas of lowland crops.

## Soil constraints

The major soil constraints were low fertility, affecting most highlands soils and the severely leached soils on the slightly higher terrain of the old terraces in the lowlands. The other widespread soil limitation was shallow depth, lateritic gravel aggregates and loss of applied nutrients during the wet season, especially on the steep slopes. In addition, they reduced the total water-holding capacity of the soil profile, limit-rooting depth, and increased the erosion hazard. The soil depth might be limited by bedrock or by dense and/or compacted lateritic gravels.

## Erosion and runoff constraints

The increase of cultivation and illegal logging in the past decades in marginal highland areas resulted in an acceleration of soil erosion and runoff.

## Technological Constraints

The physical constraints could be countered by technological measures. Such measures included irrigation, drainage flood control, system of highland agriculture and forest conservation, application of fertilizers, pesticides, weed control, improvement of seed supply and crop varieties.

## Institutional Constraints

The main institutional constraints on agricultural productivity which are typically found in developing countries with inadequate research, training, extension and availability of agricultural credit, were relatively well developed in Thailand. The government operated numerous agricultural research bodies and research stations. The Department of Agricultural Extension Service was established in each province in the capital and at the district level, and provided a reasonably effective and comprehensive service to farmers. The country had many agricultural training establishments at all levels, which provided the government with competent recruits for its various agricultural departments. The institutional credit to farmers was provided by the Bank of Agriculture and Agricultural Cooperatives (BAAC), cooperatives, farmer's welfare funds and commercial banks.

## Socioeconomic Constraints

## Social constraints

There were a few social constraints on agricultural productivity in Thailand. The Thai farmer was capable, adaptable, owner of the land, and was generally free from restrictive government control and direction. Prior to 1975, rapid population growth was the main constraint, and subsequently, the population pressure was building up on the land. This in turn led to the expansion of agricultural activity to less suitable lands.

## Economic constraints

There were a few direct economic constraints on agricultural productivity in Thailand. In addition to the widespread institutional and infrastructure support to agriculture, the government also attempted to guarantee farmer's income by imposing minimum farm-gate prices for certain crops, avoiding unnecessary restrictions on the farmers at the same time.

## Analysis of the productivity constraints

The northeastern part of the country is an important agricultural area and a significant proportion of the production of important crops came from this region. But there were productivity constraints in terms of occurrence of droughts, floods and low soil fertility causing low yields. The production constraints of the lowland, upland and highland areas in the northeastern are tabulated in Tables 21, 22 and 23 , respectively.

Table 21. Production constraints of the lowland in the northeastern region.

| Physical constraints |  |  | Technological constraints |  |  | Institutional constraints |  |  | Socioeconomic constraints |  |  |

Level of constraint: $L=$ Low; $M=M$ oderate; $H=H$ igh

## Physical constraints

## Climate

Thailand has a tropical climate and there is not much variation in the weather. The limitation is the occurrence of dry period during the rainy season. The climatic constraint could be classified as low.

## Soil

Soils in the recent past degraded because of the degradation of the land. In the northeast Thailand, the soils in the agricultural area have been found highly degraded compared to soils in the forestry area, especially in the flat plains where there is a problem of the salt expansion. The Land D evelopment D epartment (LDD 2000) reported that the salt-affected area in the northeastern with 18 million rais or about 17 percent of the region was causing a productivity constraint. So, in the K ong-C hi-M un project, salt tolerant crops and increasing the forest area were encouraged. The LD D has a target for soil improvement using 0.25 million rais of the compost of producing and providing for seed, about 8050 tons in the area of 1.6 million rais.

## Application of fertilizer

There is now an effort to move towards application of organic fertilizers because of the high cost and the polluting nature of chemical fertilizers. The Soil and Water C onservation D epartment carried out an experiment in 1999 about the use of compost in rice growing at Roi Et province. The yield was 23\% higher than the yield using chemical fertilizers. An experiment on the use of sesbania-rostrata before rice planting showed that the yield of rice was only $3.6 \%$ lower than the use of 16-16-16 fertilizer in $20 \mathrm{~kg} \mathrm{rai}^{-1}$. The Land D evelopment D epartment aims to decrease the usage of chemical fertilizers and promote the use of compost or green manure along with the promotion of soil and water conservation by the use of vetiver grass and prevention of soil erosion in 5 million rais in a year.

## Improved seeds and varieties

This constraint was low as government and private sector were working actively to distribute and sell seeds to the farmers. The Department of Agriculture, in 1994, developed the following varieties: U pland rice variety named Sew M ae Jan in Khon Kaen province and its yield was found to be about $320 \mathrm{~kg} \mathrm{rai}^{-1}$; the yield of soybean, N akosawan variety, was about $265 \mathrm{~kg} \mathrm{rai}^{-1}$ and the yield of sunflower, pacific 33 variety, was about $228 \mathrm{~kg} \mathrm{rai}^{-1}$.

## Credit

Farmers owning large landholdings had greater access to credit from government or commercial banks, whereas the small farmers with marginal landholdings rented out their land and had access only to the costlier loans from private moneylenders.

## Agricultural research

The government has a technology transfer center in each sub-district. Therefore, there was no technological constraint in the institutional mechanism for technology transfer.

## Socioeconomic constraints

There was a shortage of agricultural labor and generally the farmers with marginal landholding preferred to lease out their land. The main problem was that some crops had a minimum support price and others did not.

## Recommendations for the future interventions

- Reclamation and development of the watershed to address soil erosion problem needs to be undertaken.
- The use of organic fertilizer needs to be promoted.
- There is a need to improve the Land Development Act and improve the classification of the watershed (needs to be clarified).
- There is a need for land reforms to address the problem of inequity in the landholding structure.
- Future market needs to be developed for agricultural commodities so that the farmers have a better option of getting assured and better returns.
- There is a need to develop agro-industrial enterprises.

## Summary and conclusion

The constraint analysis of agriculture in the northeast Thailand reveals the existence of problems related to infertility of the soil, soil erosion and flooding because of the steep slope of the land. The increasing pressure of the population, which has lead to the conversion of forestland to agriculture land, has been a major reason for the above problem. The Department of $L$ and Development in Thailand admits that the magnitude of the problem is large and admits that tackling the problem in its totality requires huge budgetary support, which is a constraint. To address the budgetary constraint problem and to garner greater contribution from the farmers for soil and water conservation works, there is a need to effectively demonstrate that yield increases are possible and the gaps between the potential yields in the research plots and the farmer fields need to be reduced. These differences are currently relatively high particularly for rice ( $50 \%$ lower), maize ( $47 \%$ lower), soybean (37\% lower) and sunflower ( $6 \%$ lower).

The intervention of the project should provide the scope to demonstrate that cost-effective solutions with farmer's participation (in program conceptualization and financial support) is a possible solution. The advantage of the intervention process is the decentralized agriculture extension system in the country, which can be effectively utilized.

# Thanh Ha Watershed, Hoa Binh Province, Vietnam 

NV Viet, HM Tam, NT Chinh, NV Thang and A Ramakrishna

## Location

Thanh H a watershed is located in village \# 7 of the Thanh H a State Farm. Village \# 7 is under the administrative control of Phu Thanh Commune, Lac Thuy District, with revenue jurisdiction under Thanh H a State Farm (Figure 1).

Figure 1. Location of the watershed in Brigade \# 7, Thanh H a State Farm, H oa Binh province.

## Physical and Biological Environment

## Climate

The climate in the watershed (Figure 2) is monsoonal with hot, wet summers (April to August) and cool, cloudy, moist winters (D ecember-February). The total rainfall is $1600-2000 \mathrm{~mm}$ per annum (Figure 3). The average annual temperature is $25^{\circ} \mathrm{C}$, with an average maximum of $35^{\circ} \mathrm{C}$ (in August) and an average minimum of $12^{\circ} \mathrm{C}$ (in January). The southwest monsoon occurs during M ay to O ctober, bringing high temperatures and heavy rainfall. N ovember to M ay is the dry season with a period of prolonged cloudiness, high humidity and light rain. The length of growing season in northern Vietnam ranges from 210 to 365 days thus providing an opportunity for cropping throughout the year in some regions (Figure 4).

## Vegetation

The monsoonal tropical climate with high humidity prevailing in the rainfed sloping lands of northern Vietnam is quite favorable for forest growth and development. These are almost completely covered by the forest. At present, planted and natural forest covers only about $26 \%$. O range, litchi, Iongain, guava, papaya and custard apple are important horticultural crops while tea occupies higher altitudes.

Figure 2. C limate in watershed.

Figure 3. Rainfall at the Thanh Ha watershed.

Figure 4. Length of the growing period.

## Soils

Soils are complex and varied. The basic process of soil formation is ferralitic (through weathering of the parent material) leading to accumulation of rather high amounts of iron and aluminum, with leaching of silica and most base cations. The most common soil type is the red-yellow ferralitic. These soils accumulate iron and aluminum to form laterite. Mineralization is rapid, and organic substances quickly break down, resulting in low humus content. Intensive surface cultivation and deep leaching processes make the soil very acidic and poor in nutrients. N itrogen, phosphate and cations are easily dissolved or carried away to such an extent that these soils cannot be cultivated for long before they suffer serious degradation. In extreme cases of erosion, a hardpan of laterite nodules is exposed.

Soils in the benchmark watersheds were analyzed to a depth of 1.5 m and also based on the toposequence for physical and biological properties. Soil was medium loamy in texture, acidic in nature with very poor organic matter, medium potassium and very low phosphorous ( P ) content. Because the soils had very low organic matter and P , they are more suitable for industrial crops (tea) and fruit crops (litchi) than annual crops (maize and legumes). Soils need organic and inorganic supplements and particularly P fertilizer for good productivity if annual crops are grown. It is better to use thermophosphate than superphosphate in these soils. Total microbial population was $10^{6}-10^{8}$ CFU $\mathrm{g}^{-1}$ including bacteria, streptomycin and fungi with highest number of bacteria. Soil was rich in microbial population with large biodiversity and had good ability to develop biological activities with cultivation. Nitrogen fixing bacteria (including associated and free-living bacteria) were $10^{3}-10^{-6} \mathrm{CFU}$ $\mathrm{g}^{1}$ liter ${ }^{1}$, similar to the microbial population found in the fertile soils of Red River delta. M icrobial population at different soil depths was different in both density and diversity. Nitrogen fixing and $P$ solubilizing bacteria were $10^{4}-10^{6} \mathrm{CFU} \mathrm{g}^{1}$.

## Land Allocation

U ntil 1958, Thanh H a was a French farm known as Xa Tanh and it was under coffee plantation. Between 1958 and 1960, Vietnam army managed it with no change in the cropping system. The Thanh H a State Farm was established on 10 D ecember 1960 under the administrative control of the erstwhile Farm M inistry, but army continued to manage the farm with coffee and orange plantation until 1975. Since 1975, the farm has been transferred to the N ational Fruit and Vegetable C ompany. Starting December 1995, the State Farm came under the administrative control of Hoa Binh province. The farm was divided into 7 villages and the ownership rights were given to the farmers. The allocation of household plots and annual cropland was done with most households receiving the land where their families had historically lived and worked.

## Trends in Land Use and Livelihood Strategies

G overnment policy reforms over the past decade have attempted to re-establish the household as the basic unit of production and promote greater productivity. The Land Law of 1987, recently amended in 1993, and D ecree 327 among other legislations, facilitated the allocation of agricultural and forest land to households on a long-term basis for productive activities. New credit facilities have been made available to enable farmers to invest in upgrading the land and diversifying production, while tax policy has been adjusted to reward greater productivity. The manner in which the farm households are responding to these new opportunities, redeploying their resources and reorienting their livelihood strategies may be instructive for the future development of this region.

## Socioeconomic Conditions of the Benchmark Site

Demographic and social parameters of Thanh H a State F arm and Village \#7 are presented in Table 1. Fifty-three percent of the total land area ( 1522 ha) was suitable for agricultural purposes and only $28 \%$ was being cropped. However, $34 \%$ of the total area was under cultivation in Village \#7. Recently, most of these lands were brought under arable cropping.

| N umber of families | 868 | - | 62 | - |
| Population | 3352 | 100 | 350 | 100 |
| Female | 1732 | 52 | 182 | 52 |
| M ale | 1624 | 48 | 168 | 48 |

## Family Composition

The average family size was small with $58 \%$ of the population in the age group of 17 to 55 years. Because majority of the population was young and engaged in agricultural production, adoption of labor-intensive new production technologies and farming systems should not pose problem. The consensus among the survey participants was that their lives were better now than five years ago and anticipated that the trend of improvement in their socioeconomic condition would continue.

## Cropping Patterns and Land Use

N orthern Vietnam has four distinct seasons: spring (February-A pril), summer (M ay-J uly), autumn (A ugust-O ctober) and winter (N ovember-J anuary). Although ten different crops were grown in the watershed, major crops in terms of cropped area were maize (83\%), sugarcane (8\%), legumes (13\%) and watermelon (6\%). G roundnut was grown in the past but went out of cultivation because of severe problem of pod rot disease. Soybean was not cultivated in the watershed as no effort was made to introduce the same by the extension department. Cereal monocropping (maize-maize) was predominant and occupied $77 \%$ of the cultivated area (Figure 5). C ereal-legume cropping was only 2 $3 \%$ of the total cultivated area. Watermelon-maize cropping system was also popular (11\%).

## Input Usage

The survey on input use in various crops revealed that high quantity of inorganic fertilizers was used (Table 2). U sage of organic manure (39-46 t ha- ${ }^{-1}$ ) was limited to watermelon and sugarcane. Insecticide usage was limited to sugarcane alone.

Figure 5. C rops and cropping systems in the study area.

Table 2. Input usage in various crops in Thanh H a watershed.

| Particulars | M aize | Watermelon | Sugarcane | M ung Bean | C owpea | Rice |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Seed (kg) | 23 | 1.0 |  | 22 | 22.5 | 100 |
| Urea (kg) | 444 | 561 | 670 | 12 | Nil | 220 |
| Super phosphate $(\mathrm{kg})$ | 525 | 579 | 554 | 500 | 500 | 500 |
| M uriate of Potash (kg) | 136 | 127 | 1467 | Nil | Nil | 85 |
| M anure (t) | Nil | 46 | 39 | Nil | Nil | 10 |
| Labor (person days) | 198 | 552 | 414 | 190 | 215 | 200 |

Seed price (Dong/kg) ; maize 181,000, watermelon 554,700, mung bean 11,180; cowpea 14,000 and rice 2500 1 US\$ = 14,000 Dong

## Crop yields

The average yields of all the crops were low to moderate (Table 3) with a wide range [maize 0.9-7 t ha ${ }^{-1}$, watermel on $10-36 \mathrm{t}$ ha ${ }^{-1}$ and mung $0.3-1.2 \mathrm{t} \mathrm{ha}{ }^{-1}$. Discussions with the farmers reveal ed that production potential was high if appropriate crops and production technologies were used. Improved seed and cultural practices were being adopted in maize while production practices were at subsistence level in most other crops.

## Economics of the crops and cropping systems

Benefit cost ratios for major crops and cropping systems were worked out. Cost (C) benefit (B) analysis of various crops (Table 4 and Figures 6a, 6b) indicated that watermelon and mung bean had the highest $\mathrm{B}: \mathrm{C}$ ratio (1.78 and 1.94), while sugarcane cultivation had the lowest (1.06). Among the cropping systems, highest benefit was being realized in watermelon-maize (2.19) and mung bean-

Figure 6b. Economics of different cropping systems.
Table 5. Economics of cropping patterns of village \# 7 of Thanh Ha State Farm.

## Influence of Toposequence on Crop Productivity

The landscape watershed was divided into top, middle and lower part of the toposequence and the crop productivity differences were analyzed. M aize was grown on all the three toposequences while watermelon was grown only on middle and lower part of the toposequence. Higher benefit cost ratio was realized on the top of toposequence followed by middle and lower in maize, while lower part of the toposequence appeared to be ideal for watermelon over middle of the toposequence (Table 6).

## Landholding and Profitability Relationships

Medium landholdings (1-2 ha) were predominant (58-62\%). The relationship between size of landholding and profitability indicated that profitability reduced as the size of landholding increased in maize monocropping, while inverse relationship was noticed with watermelon-maize cropping system. Watermel on was a high input requiring commercial crop and profitability largely depended on adequate quantity and timely supply of inputs. The resource poor farmers could be facing the difficulty of meeting the crop demands in time resulting in low productivity and profitability. Secondly, marketing may not be economical in smallholdings because of high transport costs and nonavailability of market facilities in the near vicinity. N onetheless, maize input requirements were low and surprisingly small and medium landholdings invested more money over large landholdings. The

yield differences in maize could be attributed to timely operations and appropriate care provided in small landholdings than in the medium and large landholdings (Table 7).

## Landholding, Cultivated Area and Profitability Relationships

Landholding and profitability relationships in small, medium and large holdings indicated that small landholdings obtained higher profits from maize and sugarcane cropping, while large holdings obtained more profits with watermelon and rice cultivation (Table 8).

Table 7. Influence of landholding on cropping system profitability.

[^2]
## Household Capital and Income Relationships

Households were divided into poor, moderate and affluent based on the resources available (all fixed and movable assets except landholding) and influence of household capital on cropping system productivity and income generation was worked out (Table 9). M ajority of the households (72-75\%) were in poor category. Affluent farmers generated higher income over moderate and poor categories.

Table 9. Influence of household capital on income generation.

| Cropping system | Capital groups | H ousehold capital (\$) | House holds (\%) | Input ha ${ }^{1}$ <br> (\$) | Output ha ${ }^{-1}$ <br> (\$) | Benefit ha ${ }^{1}$ <br> (\$) | $\begin{gathered} \mathrm{B}: \mathrm{C} \\ \text { ratio } \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

|  | Affluent ( > 10 m ) | 1160.50 | 25 | 1422.85 | 3559.5 | 2136.65 | 2.50 |

## Influence of Inputs on Productivity and Income Generation

The productivity of a given crop or cropping system depended on adequate inputs. The profitability fluctuated with both high and low input levels. An effort was made to find out appropriate level of input requirements in the major crops of Thanh H a State Farm. For high benefit cost ratio, maize required an input of $\$ 313$, while watermelon required $\$ 938$. Sugarcane gave low profit at both low ( $\$ 1000$ ) and medium (\$1000-1429) levels and caused losses at high (\$1429) input level. M aizemaize cropping system needed an investment of $\$ 786$ for good profits, while it was better to confine investment to $\$ 1107$ in watermelon-maize cropping system as high levels of investment was deleterious (Table 10).

## Constraints to Production

The survey has brought out the following important constraints faced by the farmers in the benchmark watershed.

## Farmer perceived

- Lack of water for crop intensification (97.9\%)
- U navailability of credit and complicated loan procedures (91.8\%)
- Fertilizers are expensive (83.7\%)
- Lack of capital to purchase inputs (80\%)
- Lack of knowledge on plant protection and improved production practices (79.6\%)
- M onopoly of market forces (75.5\%)
- N on-availability of market facilities (71.4\%)
- Lack of extension services and demonstration of new technologies (71.4\%)
- Non-availability of farmyard manure (67.3\%)

Table 10. Influence of inputs on income generation.

|  | M edium (1107.14-1678.57) | 1475.00 | 1321.43 | -153.57 | 0.90 |
|  | High (> 1678.57) | 1919.07 | 1871.93 | -47.14 | 0.98 |

## Researcher perceived

- Soil erosion
- Inappropriate soil, water and nutrient management practices
- Improper land use planning
- $N$ atural resource base degradation

## Constraints and Opportunities

We examined the constraints (in the farming systems and its environment) that limit the systems productivity and made an attempt to focus on opportunities that increase the system's productivity. A number of specific challenges were identified that needed to be addressed for development to be carried out successfully in the sloping ecoregions of the northern Vietnam. A distinction was made between the constraints that in principle can be addressed directly by the research team ('addressable') and those that cannot be addressed ('non-addressable'). A priority list of constraints and opportunities identified is provided hereunder.

## Constraints

- Physical constraints: broken terrain, steep slopes and poor soils.
- Environmental constraints: deforestation, land degradation, moisture stress during critical stages of crop growth and low biological productivity.
- Infrastructure constraints: inadequate communication, transportation and production infrastructure and unskilled agricultural force.
- Economic constraints: subsistence orientation, inadequate development of market and trade.
- Cultural constraints: low levels of education and knowledge and persistence of traditional pattern of behavior.
- Intellectual constraints: inadequate scientific knowledge of the sloping land ecoregions and lack of suitable strategies to guide development and planning.

## Opportunities

- The benchmark watershed has good potential for introduction of new crops and cropping systems because the current cropping systems are giving meager income and mining the soil fertility with associated erosion of natural resource base.
- Identification and/or introduction of appropriate technologies with focus on soil, water and nutrient management at micro-level in a watershed context will help optimize food production and arrest further erosion of natural resource base.
- Farmers are currently relying on high doses of inorganic fertilizers with little or no application of organic fertilizers. Good scope exists for introduction of appropriate integrated nutrient management practices.
- M ost farmers are unaware of improved production technologies. There is a need to demonstrate new crops/cultivars, integrated pest and disease management technologies and improved crop production practices.
- Develop a paradigm tailored to the special conditions of the sloping land ecoregions.

Farmers themselves were strongly aware of some constraints, while the team members perceived other constraints. The decision on which constraints to tackle first may be influenced by this difference in perception. For example, the researchers considered soil erosion hazard as the number one problem, while farmers did not regard it as being quite serious. Erosion hazard may be seen as a 'strategic' problem, ie, one which is likely to increase in the future unless measures are taken immediately. In order to build up credibility, the team, however, decided to first address those constraints, which the farmers considered urgent, even if they were not most important from researchers' point of view.

## From Constraints to Solutions

We used several ideas and techniques from Tripp and Woolley (1989) in the analysis of constraints and goal-oriented project planning:

- A nalyzed the causes underlying the major constraints.
- Examined whether there is sufficient evidence for these causes, if not take up diagnostic research to find answers.
- Looked at whether a constraint or cause could be tackled directly by on-farm testing with available technology, if not develop the technology.
- Chose specific, well-defined technologies for on-farm testing.

The examples of groundnut and soil fertility are given in the Table 11.
Choosing the most appropriate technology always requires a good knowledge of both the target system and range of available technological options. Knowledge of the target system and the farming environment was obtained from the diagnostic survey and through collection of information. Knowledge about the technology was obtained by means of systematic search for information from experts, literature and existing databases. The following questions were also considered before planning the technol ogical options.

1. H as the target system been clearly defined in terms of location, cropping system and the type of farmer?
2. Is the specific technology adapted to the ecological conditions of the target area?
3. Will the technology contribute effectively to the solution of the problem?

Table 11. Prioritization of constraints, likely causes and research activity by the on-farm team to address them, Thanh H a State Farm, Vietnam.

| Constraint | Cause | Technology testing |  | Additional diagnostic studies |
| :---: | :---: | :---: | :---: | :---: |
|  |  | On-farm | On-station |  |
| Failure of groundnut because of pod rot | - High disease pressure | - Introduction of high yielding, disease-resistant cultivars. <br> - Introduce appropriate IPM technologies | - Screening of potential cultivars | - Quantify fungus build up and disease relationships <br> - Identify hot spots and abandon fungus-infested fields. |
| Declining soil fertility and crop productivity | - Continuous maize mono-cropping <br> - Shortening fallow <br> - Soil erosion | - Integration of legumes. <br> - Introduction of integrated land, water and nutrient management technologies | - Screening potential legumes <br> - Seed multiplication | - Characterization of soil resource |

4. D oes the technology make other contributions to the farm as a whole?
5. D oes it increase risks?
6. What does the technology require in terms of Iand, labor, cash or material investment from the farmer?
7. Does it require special extension efforts?
8. H ow does the technology fit into farmers' system, ie, where is the niche for integrating it? D oes it interfere with other parts of the system, for instance, livestock?
9. Are there other social, cultural or policy issues affecting farmer adoption?

## Farmer's Involvement in the Choice of Innovations

The research team, after carrying out the ex ante analysis of possible innovations, met the cooperating farmers and discussed the proposed innovations and solicited farmers' inputs. The average landholding in Vietnam is very small ( $1000 \mathrm{~m}^{2}$ upland or $600 \mathrm{~m}^{2}$ rice field) and the production losses if any because of improper practices advocated need to be compensated. The approach adopted therefore, is to encourage maximum participation of farmers in planning and execution of all our activities. All the watershed interventions, viz, introduction of new crops and cropping systems, soil and water conservation, IN M , IPM etc, are thoroughly discussed and decided by the farmers. Researchers and extension workers aid in decision-making process and facilitate agreed activities by providing technical support.

M icro-watershed is used as a demonstration block for appreciating the benefits in terms of reduced runoff and soil loss through scientific measurements. Farmers in rest of the watershed evaluate improved soil, water and nutrient options and cropping systems along with IPM and IDM for efficient use of natural resources and sustainable productivity gains. Studies on nutrient budgeting and micronutrients requirements for different systems are underway with close cooperation and involvement of farmers.

5. H ousehold composition

|  |  |  | Year <br> Name | Sex | Age | Daily farm <br> wages |  |  |  | Off farm <br> work | Seasonal <br> migrant | Work on <br> own farm or business |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |

6. Farm equipment

| Item | N umber | Value |
| :--- | :--- | :--- |
| Iron plough |  |  |
| Wooden plough |  |  |
| Blade harrow |  |  |
| Jumbo |  |  |
| G orru |  |  |
| Electric M otor |  |  |
| Oil Engine |  |  |
| M hote |  |  |
| Persian wheel |  |  |
| Bullock cart |  |  |
| Crow bar |  |  |
| Spade |  |  |
| Khurpi |  |  |
| Sickle |  |  |
| Axe |  |  |
| Bicycle |  |  |
| Others |  |  |
| (Specify.....................) |  |  |
| (Specify.....................) |  |  |
| (Specify....................) |  |  |
| (Specify......................) |  |  |

7. Livestock

| Species and type | N umber | Value |
| :--- | :--- | :--- |
| Bullocks (improved breed) |  |  |
| Bullocks (local) |  |  |
| M ilch cows (crossbreed) |  |  |
| Youngstock (cattle) |  |  |
| He buffaloes |  |  |
| She buffaloes |  |  |
| Youngstock (buffaloes) |  |  |
| G oats |  |  |
| Sheep |  |  |
| Pigs |  |  |
| Poultry |  |  |
| Others(specify......................) |  |  |
| (specify....................) |  |  |

III. C ropping Pattern:

| Plot SI. No./ Name | $\begin{array}{\|l\|l\|} \hline \text { Sub- } \\ \text { Plot } \end{array}$ | O wnership status ${ }^{1}$ | Crop/ Intercrop | Proportion ${ }^{2}$ | Cropped <br> Area | Season ${ }^{3}$ | Land quality | Irrigated <br> Area | Variety | Location of the plot ${ }^{4}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |

1. O wned / leased-in / share cropped-in / leased-out / share cropped-out
2. Always main crop is first
3. $K=$ kharif; $R=$ rabi; $S=$ Summer; $P=$ Perennial
4. Specify; upland, low land and normal

## Intercropping systems

D o you practise intercropping:Yes/No
If yes, what are the preferred intercropping systems.
Intercrop
(i)
(ii)
(iii) $\qquad$
A rea
(i) $\qquad$ (ii) $\qquad$ (iii) $\qquad$
I rrigated Area
(i) $\qquad$ (ii) $\qquad$
(iii) $\qquad$

Reasons for taking intercrop
1.
2.
3.

## Sequential cropping

D o you go for sequential cropping: Yes/No
If yes,

| SI. No. | Crop Sequential |  | Area | I rrigated area |
| :---: | :---: | :---: | :---: | :---: |
|  | kharif | rabi |  |  |
|  |  |  |  |  |
|  |  |  |  |  |
|  |  |  |  |  |

Reason for going to sequential crop:

## Which system has the potential for double cropping

Name of the crop: $\qquad$
Reasons: $\qquad$
$\qquad$
$\qquad$

## Sole crop

Do you plant only one crop a year in one or more plots: Yes/No
If yes:

| SI. No. | Crop | Area | Irrigated area |
| :---: | :---: | :---: | :---: |
|  |  |  |  |
|  |  |  |  |
|  |  |  |  |
|  |  |  |  |

IV. C rop disposition:

Year: $\qquad$

| Production/disposition and <br> market price | N ame of crop and season |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
|  | Crop: |  |  |  |  |  |
|  | Season: |  |  |  |  |  |
| Total production |  |  |  |  |  |  |
| G rain or main product in ....... U nit |  |  |  |  |  |  |
| Fodder or by product in ....... unit |  |  |  |  |  |  |
| D isposition |  |  |  |  |  |  |
| M arketed |  |  |  |  |  |  |
| In-kind payments to labor |  |  |  |  |  |  |
| Loan repayment |  |  |  |  |  |  |
| Still held in storage |  |  |  |  |  |  |
| Consumed |  |  |  |  |  |  |
| Other |  |  |  |  |  |  |
| Sale price, if marketed |  |  |  |  |  |  |

## V. Fertilizer and pesticide adoption:

(a) H ave you ever used inorganic fertilizer?
(b) If yes, in what year did you first start to use inorganic fertilizer?
(c) D o you apply fertilizer every year?
(d) D o you apply FYM every year? If not, how often?
(e) $\quad \mathrm{H}$ ave you ever used pesticide?
(f) If yes, in what year did you first apply?
(g) Do you own sprayer?
(h) If not, are sprayers readily available?
(i) Is fertilizer readily available throughout the year?
(j) Are pesticides readily available throughout the year?
VI. Adoption of soil conservation practices

|  | $\begin{aligned} & \pm \\ & \frac{n}{ \pm} \\ & 0 \stackrel{y}{n} \end{aligned}$ |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |
|  | $8 \text { 衣 }$ |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |

| 17. ....... |  | QT |  |  |  |  |  |

1. Labor input includes total labor days of family and hired labor for each operation. Specify male and female labor as well as bullock labor separately wherever necessary.
2. Estimate the labor requirement if you had given to contractor for harvesting.
3. Specify clearly the units (eg. $5 \mathrm{kgs}, \mathrm{FYM}-2$ tons etc.).
$M=M$ ale labor, $F=F e m a l e$ labor, $B=$ Bullock labor,
T = Tractor/Truck, TH = Thresher, SP = Sprayer, DU = D uster.
N ote a: In irrigation operation use codes from code book.
$N$ ote b: Cost of hiring tractors/bullocks includes cost of operator.
N ote c: Ask/calculate land rent for particular crop only.
IX. Sources of information

- State Agricultural D epartments
- Research Institutions (Specify)
- NGOs (Specify)
- Private Agencies (Specify)
- Relatives/Friends
- Other farmers
- Through M agazines/ N ews Papers
- Radio
- Private Seed Dealers

## X. C onstraints in production practices:

## A. Pertaining to technology YES/NO

1. Seed and seed treatment
a. Low germination
b. Low purity
c. U neven germination because of uncontrolled depth
d. Late sowing because of unavailability of seed in time
e. Complete immunity not ensured by seed treatment
f. Lack of local supply of improved seed
g. Lack of knowledge about method of sowing
h. U navailability of suitable variety as recommended
2. Water management
a. Lack of irrigation
b. U ndulated Iand
c. Lack of knowledge about irrigation method and time
d. Alternative irrigation is not possible
e. Defective land shaping
f. Water is not supplied when required
g. Stagnation of water in the field because of inadequate drainage system
h. Declining water table
3. Fertilizer and manurial management
a. Judicious balancing with recommended phosphatic and potassic fertilizer is not necessary in our soil.
b. High doses of fertilizers spoils the soils.
c. Induction of more disease and pests through application of fertilizer
d. Fertilizer application is more expensive
e. Loss of fertilizer through leaching and runoff
f. Due to poor soil conditions
g. Lack of timely supply
h. N on-availability of FYM
i. Poor quality of $F Y M$
j. Lack of timely supply of FYM
k. Lack of fertilizer supply
l. FYM is not necessary
m. FYM application
4. Weed control
a. Chemical application not effective as hand weeding
b. Difficulty in weeding in irrigated field
c. Weedicide cause toxicity to crop
d. H and weeding time and labor consuming thus expensive
e. High cost of weedicides
f. Inadequate or nil knowledge of weedicide use
5. Disease and pest control
a. Spraying is not effective
b. M ost of the diseases/pests are not controllable
c. Lack of supply of plant protection material
d. Capital insufficient
e. Lack of knowledge about plant protection
f. Lack of local supply
g. Chemicals are more toxic to the animal and human
h. No problem of disease and pest in the field
6. H arvesting and threshing
a. Difficulty in harvesting because of stagnation of water in the fields
b. Appropriate time cannot be judged
c. Lack of fruit picker

## B. Pertaining to labor management

1. Shortage of labor at the time of
2. High wages of labor at the time of
3. High labor mobilization at the time of
$\qquad$
4. Skilled/labor shortage for the purpose of

## C. Pertaining to Institutional infrastructure

1. Credit
a. N ot available from one agency and in time
b. Rate of interest is not only high but varies from agency to agency
c. Complicated loaning procedure
d. Recovery procedure is stringent
e. The various fees, charges, as well as the cost involved in running of credit agencies several times are very high
2. M arketing
a. M onopoly and forced marketing in grain market/vegetable market
b. Late and inadequate return in the market
c. M arket located at a distance place
d. M ore transportation charges
e. U nauthorized charge
3. Extension
a. Farmer training conducted at distance places
b. Improved production techniques are not demonstrated in the field
c. Intensive contact of subject matter specialist from U niversity and Agricultural D epartment with farmers in very low
d. Key information and village youth are not feed with important technical information

# Techno-economic survey for production practices and constraint analysis in watershed areas 

Name of Watershed

## G uide questionnaire for Rapid Rural Appraisal

Village information
N ame of the village
Name of the tehsil
Name of the District
Total population of village
Total cultivating households
Total labor households
Total cultivated area in village
Total fallow land in the village
Total irrigated area in the village
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

Source of irrigation
