## 2. ABSTRACT

This report encompasses the results of the following four research projects on pearl millet ergot and smut during the 1979-80 period.

1. M-Path-N2.1 (78): Studies on the biology and epidemiology of ergot (81).
2. M-Path-N2.2 (78): Identification and utilization of stable resistance to ergot (80).
3. M-Path-N2.3 (78): Evaluation of alternative ergot control measures (80).
- and 4. M-Path-N3.2 (78): Identification and utilization of stable smut resistance (80).

### 2.1 ERGOT

A considerable amount of work was done on the biology and epidemiology of ergot which led to the refinement of the ergot screening technique and to the possibility of ergot control through pollen management. Here we report our studies on the sexual and asexual stages of the ergot pathogen, *Claviceps fusiformis* Loveless, and their relative roles in the disease epidemiology.

The ergot resistance screening activities were continued and large number of materials were screened during the rainy and the post-rainy seasons at the ICRISAT Center. Considerable progress was made in developing ergot resistant lines. High levels of ergot resistance was detected in about 40 F<sub>5</sub> lines, many of which are also resistant to downy mildew and smut. These lines are being utilized in the breeding programs to develop ergot resistant hybrids and varieties.

The International Pearl Millet Ergot Nursery (IPMEN) was tested at 11 locations in India and West Africa, and the results have been reported separately (see the 1979 IPMEN report PMPE 8001).

The evaluation of the possibilities for control of ergot through pollen management has given encouraging results. This control measure seems to be practical and is probably economical at the farmers' level.

## 2.2 SMUT

The smut resistance screening activities continued at the ICRISAT-HAU farm at Hissar during the 1979 rainy season. Although the weather was not conducive for high natural smut incidence, successful screening was facilitated by artificial inoculation. Many lines with high levels of smut resistance were identified.

The 1979 International Pearl Millet Smut Nursery (IPMSN) was tested at four locations in West Africa and India and lines with stable smut resistance have been identified (see the 1979 IPMSN report PMPS: 8001). These lines are being utilized in the breeding program to develop smut resistant hybrids and varieties.

The results of each project are reported separately in the following pages.

## ERGOT

3 Project M-Path-N2.1 Studies on the biology and epidemiology of ergot3.1 Summary

- i) - ergot sclerotia varied in size (6.05 mm x 1.75 mm to 3.55 mm x 1.25 mm), surface texture (smooth to rough), compactness (compact to brittle with cavities), shininess (bright to dull) and in color (brown to dark brown).
- ii) - sclerotial germination was not related to sclerotial size nor to manner of placement in the soil. However, older sclerotia (more than 1 yr old) germinated earlier (within 45 days) than freshly collected sclerotia (less than 6 months old).
- iii) - perithecia, asci, and ascospores from germinated sclerotia were examined carefully and were photographed.
- iv) - ascospores from the germinated sclerotia were trapped on sticky slides.
- v) - in a field experiment in the 1973 rainy season the positive role of ergot sclerotia in primary ergot infection was demonstrated. The hybrid ICH-105 planted with sclerotia developed ergot infection earlier than the ICH-105 planted without sclerotia in two isolation plots. Many sclerotia germinated at the time when flowering commenced in the hybrid. Supportive results were obtained in a pot experiment.
- vi) - the ergot pathogen, *Claviceps fusiformis* Loveless, was successfully cultured on Kirchoff's, ammonium citrate, and potato-dextrose-agar (PDA) media, both on semi-solid and broth media. Scanty mycelial growth with numerous macro- and few micro-conidia were observed on these media at 25 C. Conidia produced on Kirchoff's medium were longer than those produced on ammonium citrate or PDA.

- vii) - honeydew conidia germinated faster than sclerotial-borne conidia - about 30% honeydew conidia germinated in 24 hr compared with 3% germination in sclerotial-borne conidia after 120 hr of incubation at 25 C in sterile distilled water. Germination of sclerotial-borne conidia was influenced by concentrations of sucrose solution - 5% sucrose solution produced 19% germination compared with 4% germination in 1% sucrose solution at 25 C.
- viii) - inoculation with fresh honeydew conidial suspension produced more ergot (59% infection index) than sclerotial-borne conidia in 5% sucrose solution (22% infection index).
- ix) - the significant interaction between ergot conidia and pearl millet pollen was further confirmed which led to the improvement of screening technique and possibility of ergot control through pollen management (Thakur & Williams, 1980. *Phytopathology* 70:80-84)

### 3.2 Introduction

This project was initiated in 1976 and the progress was reviewed in 1978. Since then a great deal of work has been done. We concentrated our efforts in understanding the sexual and asexual life cycles of the pathogen and the role of sclerotia and conidia in disease epidemiology.

### 3.3 Sclerotial germination

*Claviceps fusiformis* sclerotia were collected from infected earheads of several cultivars and were examined for variability in size (Fig. 1), surface texture, compactness, and color. The sizes varied from 3.55 mm x 1.25 mm to 6.05 mm x 1.75 mm, surface texture varied from smooth to rough, compactness varied from very hard, compact to brittle, non-compact with cavities, and color varied from light-brown to dark-brown. Transverse sections of sclerotia showed a dense pseudoparenchymatous tissue, hyaline in the interior and black on the periphery, with irregular cavities in the center (Fig. 2).

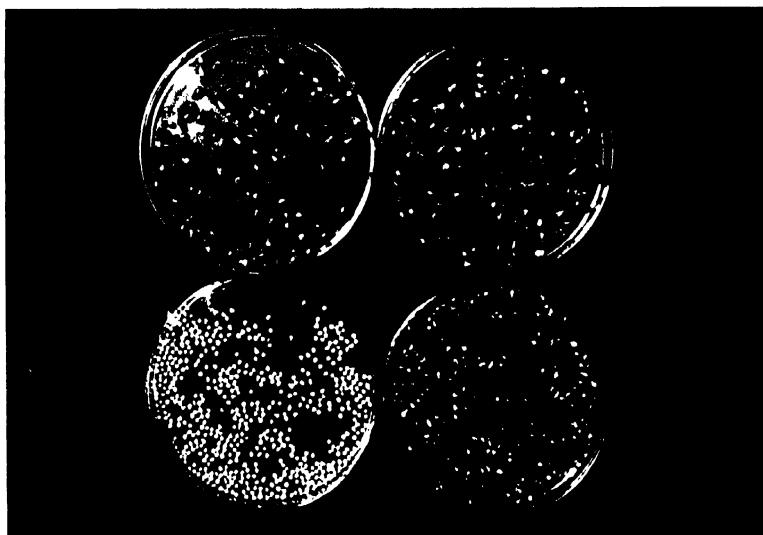

Fig. 1. Variable sizes of sclerotia of *Claviceps fusiformis* Lov. compared to pearl millet seed size

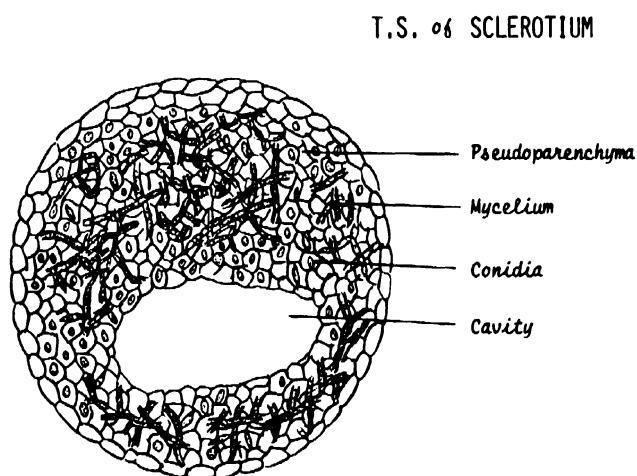

Fig. 2. Structure of sclerotium of *Claviceps fusiformis* Lov.

Sclerotia of different ages, shapes, sizes, colors and compactness were compared for germination. Sclerotia were placed in autoclaved sand in plastic petriplates, either vertically or horizontally and completely buried or partially buried. The plates were incubated at 25 C and the sand was kept moist by frequent watering with sterile distilled water. Observations for sclerotial germination were made at 30, 60, 120 and 165 days after incubation. A small proportion of sclerotia germinated 30 days after seeding. Germination was erratic. Maximum germination (52%) was recorded 165 days after incubation of the 1-year-old, large sclerotia, completely buried horizontally. But this was not confirmed in subsequent tests, based on which the conclusion was made that the methods of sclerotial placement (vertically or horizontally), degree of burial (partial or complete), compactness and colours had no effect on germination.

Sclerotia germinated by producing 3 to 8 fleshy, purplish stalks (6 to 25 mm long). Each stalk terminates in a globular head, called stroma which is light brown (Fig. 3). The stalks first appear as small swellings on the surface of the sclerotium and as the outer dark-colored layer gradually ruptures, the light colored heads of stroma protrude. The development of each stroma is due to the outgrowth of a tuft of hyphae from the inner tissue of the sclerotium. When a mature stroma is crushed on a glass slide with the help of coverslip in a drop of lactophenol and examined microscopically, flask-shaped perithecial structures are seen with ascii emerging through an ostiole. The ascii are long, ostiolate, with a hyaline narrow end. Each ascus contains long thread-like ascospores (Fig. 4).

Many ascospores were collected on a strip of cellophane tape exposed to the mature stromata.

### 3.4 Role of ascospores in ergot epidemiology

Results of preliminary experiments conducted in isolation plots and in pots indicated the positive role of ascospores in the disease

GERMINATED SCLEROTIUM

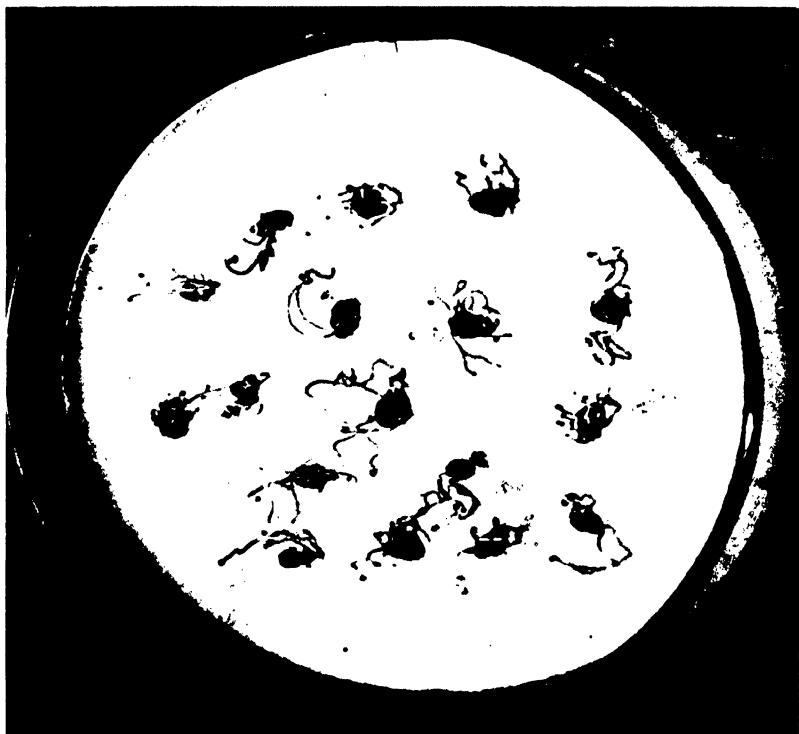

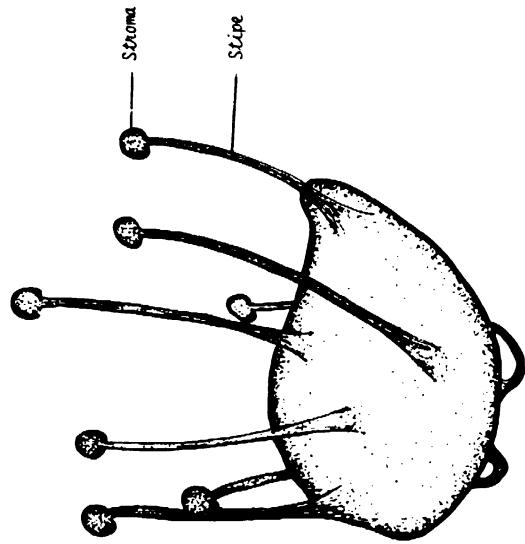

Fig. 3. Structure and germination of sclerotia of *Claviceps fusiformis* Lov.

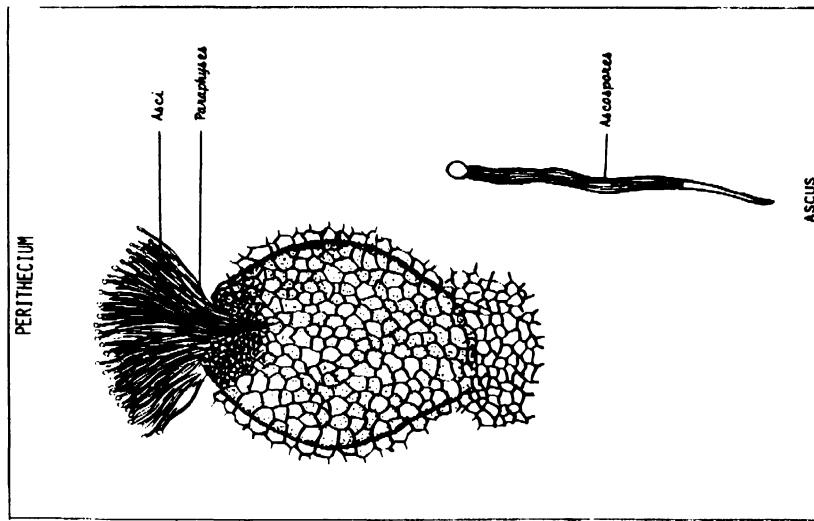

Fig. 4. Structure and production of perithecia, ascii and ascospores of *Claviceps fusiformis* Lov.

epidemiology. Pearl millet hybrid ICH-105 was planted with and without ergot sclerotia in isolation plots (14 rows x 10m). About 25 sclerotia in perforated plastic cups were buried at 1m intervals in the alternate rows of ICH-105. The other isolation plot planted with ICH-105 was without sclerotia. Many sclerotia germinated when flowering started in ICH-105. Four days later about 2% inflorescences were infected in the sclerotial plot compared with no infection in the ICH-105 plot without sclerotia.

Coincidence of sclerotial germination with flowering time in ICH-105, 5141A and BJ-104 was also observed in a pot experiment.

Severe ergot developed when protogynous inflorescences were exposed to the germinated sclerotia in pot soil under controlled conditions. This needs further confirmation.

### 3.5 Isolation of the pathogen (*Claviceps fusiformis*)

Culturing the pathogen on artificial media and maintaining its purity is an important routine work in a pathological laboratory. A pathogen keeps on evolving its new types to suit the changes in the host varieties and environment for its better survival. To know the changes in the pathogen and its distribution in the areas where the host crop is grown it is important to maintain it in its pure form.

During the year, attempts were made to isolate the fungus on various synthetic and non-synthetic media, to select the one most suitable for the growth of the fungus, to test the pathogenicity of the cultures, and to maintain pure cultures for further studies.

Isolation of the fungus from the honeydew was tried on the following synthetic and non-synthetic media: a) Kirchoff's medium (KM):- sucrose (100 g),  $\text{KH}_2\text{PO}_4$  (1 g), asparagin (1 g),  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$  (0.25 g), agar (15 g) and water (1 litre); b) Ammonium citrate medium (ACM):-  $\text{CA}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  (1.44 g),  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$  (1.51 g),  $\text{KCl}$  (0.125 g), di-basic ammonium citrate (20 g),  $\text{KH}_2\text{PO}_4$  monobasic (0.1 g), sucrose (200 g), and water (1 litre);

c) Potato-dextrose agar (PDA):- Potato (200 g), dextrose (15 g), agar (15 g), and water (1 litre); d) Pearl Millet floret extract-sucrose-agar medium (PSA):- Green florets (200 g), sucrose (15 g), agar (15 g) and water (1 litre); and e) Nutrient agar (NA);- Peptone (10 g), beef extract (5 g), agar (15 g), and water (1 litre).

Scanty mycelial growth with numerous macro-conidia and comparatively few micro-conidia were observed on KM, ACM, and PDA but no growth was observed on PSA and NA.

Mycelial fragments from the above cultures were further transferred to KM, ACM, and PD broth in 100 ml flasks and were incubated at 25 C. Mycelial development was quite rapid in all the broths and thick mycelial mats covering the entire broth surface area were observed 1 month after incubation.

Isolation of the fungus was also attempted from sclerotia by sclerotial plating. Sclerotia were washed thoroughly under running tap water, dipped in 95% alcohol for 2 min, surface sterilized with commercial chlorox (5.25%) for 10 min, cut into two or three pieces and were seeded on PDA plates. White mycelial growth from peripheral surface of the sclerotial pieces was observed 5 days after incubation at 25 C. These mycelial fragments were transferred to KM, ACM, and PDA slants and incubated at 25 C. The cultures of the fungus are maintained at 10 C in a refrigerator.

### 3.6 Pathogenicity tests

The fungal cultures from KM, ACM, and PD broth were diluted with sterilized distilled water to the concentration range of  $1 \times 10^3$  to  $1 \times 10^4$  conidia/ml). Several heads of a male-sterile line, 111-A, were dip-inoculated at protogyny and bagged with parchment paper bags. Slimy turbid droplets of honeydew were observed on florets 4 days after inoculation. Cultures from all the three media were infective but the KM-broth

culture produced maximum infection (53%) compared with 30% infection with PDA culture and 23% infection from ACM culture. The fungus was re-isolated from these infected heads on KM, ACM, and PDA slants and incubated at 25 C. Mycelial growth, and measurements of both macro- and micro-conidia were similar to the original culture.

### 3.7 In-vitro germination of macro- and micro-conidia

Both macro- and micro-conidia from honeydew were examined for germination in sterile distilled water in cavity slides at 25 C. Macro-conidia germinated by producing a germtube from either end. The germtubes produced septa at the tips before producing on them macro- or micro-conidia. Micro-conidia were produced in chains from the tips of the germ-tubes (Fig. 5).

Germination (viability) of honeydew conidia and sclerotial conidia (mostly micro-conidia) was compared in different concentrations of sucrose solution in cavity slides at 25 C. The honeydew conidia were more viable (30.3% germination 24 hr after incubation) than the sclerotial conidia (no germination even 96 hr after incubation). At 120 hr after incubation the maximum germination of the sclerotial conidia was 19.2% in 5% sucrose solution compared to 60.4% germination for the honeydew conidia.

4 Project M.Path-N2.2: Identification, development and utilization of stable resistance to ergot

4. Summary

4.1.1 Initial Screen:-

- i) - about 1,000 lines, including African germplasm lines selected from Upper Volta, were screened. About 64% of the lines developed more than 50% ergot and only about 3% of the lines had no more than 20% ergot. We selected 180 ergot less susceptible (<2% severity) single heads for further testing.
- ii) - of 509 entries from 16 ICRISAT Pearl Millet Breeding trials about 85% of the entries had more than 50% ergot and only about 3% of the entries had ergot between 11 and 30%.
- iii) - of the 149 All India Coordinated Millet Improvement Project (AICMIP) trial entries, no entry had less than 40% ergot, and 97% of the entries had more than 50% ergot.

4.1.2 Advanced Screen:-

- i) - a total of 751 ergot-free single heads selected from the 1978 Initial and Advanced Screens were evaluated as head-to-row progenies. About 16% of the lines developed a mean ergot severity of no more than 20%. About 100 ergot-free single heads were selected for further testing.
- ii) - twenty ergot-free heads, with overlapping of anthesis and protogyny selected during the 1979 rainy season, were screened during the 1979-80 post rainy season as head-to-row progenies. No line was ergot-free, but 11 of the 20 lines had ergot in the range of 5 to 9%, and the remaining entries had ergot between 13 and 31% (compared to 76% ergot in the susceptible check BJ-104).

- iii) - selfed and sibbed progenies of 19 IPMEN entries were tested for ergot reactions, to determine which the superior method of seed increase without affecting resistance levels of the entries. Ergot reactions were variable and no conclusion could be drawn.
- iv) - of 23 entries tested in the 1979 Pearl Millet Ergot Nursery (PMEN), only 2 entries developed very low ergot (3% and 4%). The remaining 21 entries had ergot in the range of 12 to 89%. We selected 40 ergot free single heads for further evaluation.

#### 4.1.3 Development of Ergot Resistance

- i) - more than 2600 lines, consisting of  $F_5$ ,  $F_4$ ,  $F_3$ ,  $F_2$  and  $F_1$  lines from crosses involving ergot low susceptible genotypes and between ergot low susceptible and agronomic elite lines, were screened and selections made.
- ii) - at the  $F_5$  stage 40 lines with high levels of ergot resistance (<10% severity) were identified. Many of these lines were resistant to downy mildew (DM) and smut in the DM-nursery at ICRISAT Center and smut nursery at Hissar. Twenty of these lines were included in the 1980 IPMEN for multilocational testing.
- iii) - five of the most ergot resistant lines were intermated to further increase the levels of resistance in the progenies.

#### 4.1.4 International Pearl Millet Disease Resistance Testing Program (IPMDRTP) and Multiple Disease Resistance:-

- i) - the IPMEN with 27 entries was tested at Kamboinse in Upper Volta and at 10 locations in India. Promising entries at and across locations were identified (see the 1979 IPMEN Report PMPE 8001). These entries were also screened for downy mildew and smut reactions in the DM-nursery at the Center and in the smut nursery at Hissar, and entries with resistance to ergot, downy mildew and smut were identified.

- ii) - the 45 entries in the 1979 International Pearl Millet Downy Mildew Nursery (IPMDMN) were screened for ergot and smut reactions in the ergot nursery at the Center and in the smut nursery at Hissar, and lines with multiple disease resistance were identified.
- iii) - the 1979 IPMSN with 37 entries was screened for ergot and downy mildew reactions, and several lines with high resistance to smut, ergot and downy mildew were identified.
- iv) - 13 lines from IPMDMN, IPMEN and IPMSN had high levels of resistance to downy mildew, ergot, and smut.

#### 4.1.5 Utilization of identified/developed resistance sources:-

- i) - 30 ergot resistant  $F_5$  lines were test-crossed to 3 ms lines to test the potential of using them as pollinators in the hybrid program.
- ii) - 12 of the ergot resistant  $F_5$  lines were used to form 2 synthetics.
- iii) - Crosses were made between ergot resistant  $F_5$  lines and ergot susceptible inbreds to study the genetics of ergot resistance.
- iv) - ergot resistant  $F_5$  seed have been supplied to national program scientists on request.

#### 4.2 Introduction

This project was initiated in 1976 and the progress was reviewed in 1978. The main objectives of this project are to identify and develop ergot resistance sources and utilize them in breeding programs to develop ergot resistant hybrids and varieties.

Screening of germplasm lines and breeding materials is the basic activity in identifying sources of resistance. As reported in the earlier years' reports our screening activities have three phases - initial, advanced, and multilocational. The detailed screening procedures and scoring methods were reported earlier.

#### 4.3 Initial Screen

##### 4.3.1 Germplasm lines:-

- i) - of 284 germplasm lines from Cameroon, Mali, Senegal, and Niger, no line was ergot free, 5 and 8 lines had ergot in the range of 11 to 20%, and 21 to 30%, respectively, and the remaining 271 (95% of the lines) had more than 40% ergot (Table 1). The detailed ergot reactions of individual entries are presented in Appendix-I. Twentysix ergot-free single heads were selected for further testing.
- ii) - of 84 germplasm selections by Clement in Upper Volta, no line was ergot-free, 2 and 5 lines developed ergot in the range of 11 to 20% and 21-30%, respectively, and the remaining 77 lines (92% of the lines) had more than 40% ergot (Table 2). Ergot reactions of individual entries are presented in Appendix-II.

##### 4.3.2 Breeding materials

- i) - Selections from Upper Volta:- Of 651 selections from the breeding lines at Upper Volta, no line was ergot-free, 6 and 13 lines had ergot in the range of 1-10% and 11-20%, respectively. The majority of lines (more than 68%) developed more than 50% ergot (Table 3). Ergot reactions of individual entries are presented in Appendix-III. We selected 152 ergot-free single heads for further testing.
- ii) - ICRISAT breeding lines:- A total of 509 lines including hybrids, populations, inbreds, and male steriles from 16 trials were screened. No line was ergot-free, only 3 lines (0.6% of the lines) and 12 lines (2.3% of the lines) had ergot in the range of 11-20% and 21-30%, respectively, and about 85% of the lines had more than 50% ergot. The performance of entries in each trial are summarised in Table 4, and the individual entry reactions are presented in Appendix-IV. Almost all hybrids, ms-lines, and their pollinators were highly susceptible (>90% ergot).

iii) - AICMIP trials:- Five trials with 149 entries including hybrids, populations, ms-lines, and their pollinators were screened. The performance of the entries in each trial is summarised in Table 5, and ergot reactions of individual entries in each trial are presented in Appendix-V. A detailed report was prepared and circulated in the AICMIP workshop at Hissar, April 1980. Of 52 hybrids only 3 had ergot in the range of 41 to 50%, and the remaining 49 hybrids developed ergot in the range of 55 to 97%.

Among the populations only 2 of the 46 populations had less than 50% ergot (MCC 75-46% and MCP 76-49%), and the remaining 44 populations had ergot in the range of 51 to 92%. The two promising populations PSB-8 and WCC-75 developed 63 and 51% ergot, respectively.

Of the 49 ms and pollinators, ms-lines 5509-A, 3972-A, and 6104-A, which appeared promising with only 2, 13 and 18% ergot, respectively, during the 1979 rainy season, all developed more than 50% ergot when retested during the 1979-80 post rainy season. The two most commonly used ms-lines 5054-A and 5141-A developed 82 and 91% ergot respectively.

A total of 1677 lines including germplasm lines and breeding materials were screened in the initial screen. No line was ergot-free, only 29 lines (1.7% of lines) had ergot in the range of 1 to 20% and the majority of lines (74% of lines) developed more than 50% ergot. The performance of lines is summarised in Table 6.

#### 4.4 Advanced screen

Ergot-free single head selections from the Initial Screens are rescreened as head-to-row progenies in the Advanced Screen.

About 800 selections were screened in seven trials, which are reported below.

- 4.4.1      Advanced Screen-A:- Of 256 selections screened, no selection was ergot-free, 4 and 13 selections developed ergot in the range of 1 to 10 and 11 to 20%, respectively, and 160 selections (about 62% of the entries) had more than 50% ergot (Table 7). The detailed ergot reactions are provided in Appendix-VI.
- 4.4.2      Advanced Screen-B:- Of 98 selections in this group, 1 selection had less than 1% ergot, 15 selections had ergot in the range of 1 to 20% and 48 selections (49% of the selections) had more than 50% ergot (Table 8). The detailed ergot reactions are provided in Appendix-VII.
- 4.4.3      Advanced Screen-C:- Nine of the 37 selections had ergot in the range of 1 to 20%, 24 selections developed ergot between 21 and 50% and only 4 selections had more than 50% ergot (Table 9, Appendix-VIII).
- 4.4.4      Advanced Screen-D:- Twenty-seven of the 204 selections developed ergot in the range of 1 to 20% and 87 selections (43% of the selections) had more than 50% ergot (Table 10, Appendix-IX).
- 4.4.5      Advanced Screen-E:- Single head selections made for overlapping of anthesis and protogyny in the downy mildew nursery during the 1978-79 post-rainy season, were rescreened as head-to-row progenies during the 1979 rainy season. Of 113 selections, 1 selection had less than 1% ergot, 10 selections had between 1 and 10% ergot and 15 selections had between 11 and 20% ergot (Table 11). We selected 92 ergot-free single heads from 32 selections for further testing. The detailed reactions are presented in Appendix-X. These 92 single head selections were grown during the post-rainy season 1979-80 as head to row progeny. Mean ergot severity, severity range and downy mildew reactions of the 20 ergot-least-susceptible entries are provided in Table 12. Eleven of the 20 entries had ergot in the range of 5 to 9% and were downy mildew free. Selections from these lines will be tested during the 1980 rainy season.

4.4.6      PMEN:- Twenty three entries selected from the 1978 Advanced Screen were retested in a replicated trial during the 1979 rainy season. SC-2(M)5-4-E-1-T-2 and 700708-1-E-1 had mean ergot severities of 3 and 4% respectively, 3 entries developed ergot between 12 and 13% and the remaining 18 entries had ergot in the range of 22 to 89% (Table 13). We have selected 41 ergot-free heads for further testing.

4.4.7      Selfed and sibbed entries:- Seed of 19 entries was increased by selfing and sibbing during the post-rainy season 1978-79, and were tested for their ergot reactions during the 1979 rainy season. This was done to determine whether the seed of ergot resistant lines could be increased by selfing or sibbing, without affecting the ergot susceptibility levels. Data presented in Table 14 indicate no definite relationship between selfing, sibbing and ergot reactions. It may be useful to maintain the seed of ergot resistant lines by selfing so that resistant inbreds could be produced which will be easy for utilizing in the breeding program.

A total of 751 single head selections from the 1978 initial screens were screened as head-to-row progenies in the 1979 advanced screen. About 7% of selections (51 entries) had ergot in the range of 0 to 10% and many ergot-free single heads were selected from these entries for further evaluation. The performance of entries is summarised in Table 15.

4.5      Development of Ergot Resistance:-

By the end of the 1976 rainy season more than 4,000 germplasm lines had been screened with no source of high level of ergot resistance detected. In an attempt to assemble scattered resistance genes, twenty pearl millet lines, identified as apparently less susceptible in the 1975 and 1976 screenings, were intermated during the 1976-77 post-rainy season to give 269 F<sub>1</sub> progenies. F<sub>2</sub> populations were screened during the 1978 rainy season, and ergot-free single-head selections from them were screened as F<sub>3</sub> lines during the 1978-79 post rainy season. Ergot-free single head selections (F<sub>4</sub>s) from the F<sub>3</sub> lines were similarly screened during the 1979-rainy season, and F<sub>5</sub> lines were screened during the 1979-80 post rainy season (Table 16).

The results of these tests indicate that considerable progress has been made in developing lines that have a high degree of ergot resistance that is effective under severe inoculum pressure. The degree of progress is summarized in Table 17.

Every season, lines identified as ergot low susceptible, are intermated and the progenies screened and ergot-free single heads selected. During the 1979 rainy season about 1500 lines, in F<sub>1</sub> (71 lines, Appendix-XI), F<sub>2</sub> (92 populations, Appendix-XII), F<sub>3</sub> (F<sub>31</sub>-95 lines, Appendix-XIII); F<sub>3</sub> 11-160 lines, Appendix-XIV; F<sub>3</sub> III-136 lines, Appendix-XV; and F<sub>3</sub> IV-74 lines, Appendix-XVI) and F<sub>4</sub> (F<sub>4</sub> 1-258 lines, Appendix-XVII; F<sub>4</sub> II-214 lines, Appendix-XVIII; and F<sub>4</sub> III-401 lines, Appendix-XIX) stages were screened and selections were made. Performance of these lines at different stages is summarised in Table 18. In the 1979-80 post-rainy season 1149 lines in F<sub>2</sub> (29 populations, Appendix-XX), F<sub>4</sub> (280 lines, Appendices-XXI-XXIV) and F<sub>5</sub> (840 lines, Appendices XXV-XXVI) stages were screened and the performance of these lines is summarised in Table 19.

From the first set of crosses, the 20 ergot-least-susceptible F<sub>5</sub> lines have been included in the 1980 IPMEN for multilocational testing in India and West Africa (Table 20).

#### 4.6 IPMDRTP and Multiple Disease Resistance:-

The International Pearl Millet Disease Resistance Testing Program (IPMDRTP) was initiated in 1976 with the IPMDMN, and included the IPMEN and the IPMSN in 1977, and the IPMRN in 1978.

4.6.1 The 1979 IPMEN:- The 27 entry IPMEN was tested at 11 locations in India and West Africa. A separate report has been brought out and distributed to the scientists concerned (see the Progress Report: PMPE 3001). In addition to ergot screening, the IPMEN entries were screened for downy mildew resistance and smut resistance at the ICRISAT Center and at Hissar respectively. Many of the IPMEN entries had high levels of resistance to downy mildew and smut (Table 21).

4.6.2      The 1979 IPMDMN:- The 45 entry IPMDMN was screened for ergot and smut resistance in addition to downy mildew resistance and entries with low susceptibility to ergot, smut and downy mildew were identified (Table 22).

4.6.3      The 1979 IPMSN:- The 37 entry IPMSN was screened for ergot and downy mildew resistance in addition to smut resistance and entries with low susceptibility to smut, ergot and downy mildew were identified (Table 23).

At the ICRISAT Center, lines identified resistant to one disease are screened for other diseases. From the 1979 IPMEN, IPMDMN and IPMSN we have 13 lines with good levels of resistance to downy mildew, smut, and ergot (Table 24). and by the end of 1980 we expect more lines with multiple disease resistance including rust resistance.

The ergot resistant  $F_4$  lines were screened for downy mildew and smut resistances in the 1979 rainy season, and lines with high levels resistance to ergot, downy mildew, and smut were identified (Table 25).

Each set of crosses for ergot resistance is exposed to the high inoculum pressure of downy mildew and smut at  $F_4$  or  $F_5$  stage and lines with multiple disease resistance are identified.

#### 4.7 Utilization of developed resistance sources:-

After the sources of resistance have been developed, the next important step is to effectively utilize the resistance to develop disease resistant hybrids and varieties. We have been doing this in collaboration with our breeding colleagues. During the 1979-80 post rainy season the ergot low susceptible  $F_5$  lines were planted in the downy mildew nursery for (i) screening for downy mildew resistance (ii) increasing seeds of the ergot least susceptible lines by selfing the downy mildew-free plants, and (iii) utilization in the breeding program.

Dr. B.S. Talukdar and his group made 642 test-crosses on 3 ms lines (111-A, 5141-A, and 5054-A) using the top 30 ergot least susceptible and DM resistant  $F_5$  lines to test their potential as pollinators in the hybrid program.

Dr. S.B. Chavan and his group used 12 ergot least susceptible and DM resistant  $F_5$  lines to form 2 synthetics.

Crosses were made between susceptible and resistant inbreds to study the genetics of resistance.

Table 1. Performance of 284 West African germplasm lines in the initial ergot screen during the 1979 rainy season at ICRISAT Center

5. Project No.: M-Path-N2.3: Evaluation of alternative ergot control measures5.1 Summary:-

The concept of the "pollen-based ergot escape mechanism", which emerged from the discovery of interaction between pollen and ergot conidia, was tested to control ergot in hybrids.

Provision of timely supply of pollen from an early-maturing ergot-less-susceptible genotype, SC-2(M)5-4, to the highly ergot susceptible hybrids ICH-118 and ICH-220 reduced ergot infection and increased grain yields in inoculated isolated field plots. Results indicate that this control measure could probably be effectively and economically applied to control ergot in hybrids in farmers' fields.

5.2 Introduction:-

This project was initiated in 1978, with the objective to evaluate the possibility of an effective method, other than the host-plant resistance, to control ergot in pearl millet. This particular project was the outcome of our finding that rapid pollination reduces ergot infection (Thakur & Williams, 1980, *Phytopathology* 70: 80-84). We hypothesized that increasing pollen availability at the stage of maximum susceptibility in an F<sub>1</sub> hybrid would reduce ergot infection.

5.3 Experiments and Results:-

The experiments were conducted during the rainy seasons of 1978 and 1979 at the ICRISAT Center farm in isolated plots. Two ICRISAT experimental F<sub>1</sub> hybrids, ICH-118 and ICH-220, were the susceptible test hybrids. A African variety, SC-2(M)5-4, early maturing and less susceptible to ergot, was used as the pollen donor. The test hybrids were planted as a sole crop and either as a seed mixture (4 part hybrid + 1 part pollen donor) or in combination and the pollen donor planted after every 2 rows of the test hybrid. The following treatments were maintained.

hybrid alone - inoculated  
hybrid + pollen donor - inoculated  
hybrid alone - noninoculated  
hybrid + pollen donor - noninoculated

The experiments were conducted in 24m x 20m isolation plots located atleast 500 m from any other pearl millet crop. In 1978, the test hybrid used was ICH-118 as seed mixture with the pollen donor in an unreplicated trial. In 1979 ICH-220 was used with the pollen donor planted after every 2 rows of the hybrid. Ergot inoculations were made by spray-inoculating the crop at the time the hybrid was at the protogyny flower-ing stage with honeydew conidial suspension using a knapsack power sprayer. The inoculations were made thrice in 1978 and twice in 1979. Water was sprayed on the noninoculated check crops.

Ergot scoring and yield measurements were taken following the standard procedures used at the ICRISAT Center.

Results of two years experiments are presented in Tables 26 and 27. In both the years in inoculated plots there was a considerable reduction in ergot infection and increase in grain yields of the hybrids planted with the pollen donor compared with the hybrids without the pollen donor.

While these results are encouraging, there is a need to test the success of this control measure at more than one location..

Table 26. Ergot infection and grain yield of Pearl Millet F<sub>1</sub> hybrid ICH-113 grown with and without a pollen donor, SC-2(M)5-4 and either inoculated or non-inoculated in four isolation plots during the 1978 rainy season at the ICRISAT Center

6 Project: M.Path-N3.2: Identification, development and utilization of stable smut resistance

6.1 Summary:-

Smut resistance screening has been carried out at Hissar since 1977. Although Hissar is known as a "hot spot" for smut, natural incidence of smut was almost negligible during the 1979 rainy season. The weather conditions, particularly humidity although were not conducive to promote natural smut infection, about 40% infection (severity) developed on the known susceptible hybrids BJ-104 and ICH-105 following inoculation.

6.1.1 Initial Screen:-

- i) - of 358 West African germplasm lines (including Clement selections), 93 lines were smut-free and about 52% of lines had smut in the range of 0.1 to 5%. Many smut-free single heads were selected for further testing.
- ii) - of 654 selections from Upper Volta, 48 lines were smut-free and more than 50% of the lines had no more than 5% smut.
- iii) - a total of 99 entries in 5 ICRISAT breeding trials were screened. All the hybrids and male steriles were highly susceptible (more than 20% smut). Six of the 23 inbreds were smut-free. High smut susceptibility of the advanced breeding lines emphasises the need to develop smut resistant hybrids and varieties.

6.1.2 Advanced Screen:-

- i) - 790 entries, selected from the 1978 Initial Screen were tested. Twentyone percent of entries were smut-free, about 30% of entries had smut between 0.1 and 1%, 26% of entries had smut severity between 1.1 and 5%, and only about 3% of entries had beyond 20% smut. Some of the smut-free entries have been included in the 1980 IPMSN for multilocational testing.

- ii) - in the 23 entry PMSN (entries selected from the 1978 Advanced screen) 5 entries were smut-free and 22 entries had no more than 5% smut. Some of these entries were included in the 1980 IPMSN.

#### 6.1.3 The 1979 IPMSN:-

- the 1979 International Pearl Millet Smut Nursery (IPMSN), with 37 entries, was tested at 2 locations in West Africa and 2 locations in India. Entries with a high degree of resistance across locations were identified (see the 1979 IPMSN Report - PMPS 8001).

#### 6.1.4 Development of smut resistance:-

- a total of 167 F<sub>2</sub> populations from crosses involving smut low susceptible genotypes and agronomic elite genotypes were tested. More than 500 smut-free single heads were selected from the promising populations for further evaluation at the F<sub>3</sub> stage.

#### 6.1.5 Utilization of smut resistance:-

- some of the identified resistance sources are being utilized to develop smut resistant hybrids and varieties. Test cross F<sub>1</sub>s and Co-bulks will be tested during the 1980 rainy season. Crosses between smut resistant lines and good agronomic types (dwarf and high tillering) have been made and F<sub>2</sub> populations will be screened in the 1980 rainy season.
- seed of smut resistant lines have been supplied to several scientists in India on request.

#### 6.2 Introduction:-

This project was initiated in 1976 and the progress was reviewed in 1978. The main objectives of the project are to identify and develop sources of resistance, and utilise them in breeding program to develop smut resistant cultivars.

Smut resistance screening has been carried out since 1977 at Hissar, a smut "hot spot" location. Like the ergot resistance screening, the smut resistance screening is also carried out in three phases - Initial, Advance and Multilocational testing as detailed in the 1978 Report.

During the rainy seasons of 1977 and 1978, the natural incidence of smut was high enough (more than 80% severity on susceptible lines) at Hissar for screening materials without artificial inoculation. Natural smut incidence, however, was quite low (less than 1% on the early planted smut susceptible hybrid BJ-104 at HAU farm) during the 1979 rainy season. Therefore, screening was done by artificial inoculation. The inoculated heads of BJ-104 and ICH-105 developed about 40% smut compared to less than 1% smut on uninoculated heads.

#### 6.3 Inoculum and inoculation:-

Spore balls from freshly collected smut sori, from infected earheads at the HAU farm, were soaked in tap water for about 24 hrs. The sporidial suspension so obtained was used as inoculum. About 5 ml spore suspension was inject-inoculated into the boot of each plant and was then covered with a white parchment paper bag. Smut scoring was done at maturity. The scoring system followed was the same as in the previous years.

#### 6.4 Initial Screen:-

6.4.1 Initial Screen-A:- 274 germplasm lines from Africa were screened. Seventy five lines (27% of entries) were smut-free and only 8 lines had more than 20% smut (Table 28). Detailed smut reactions are provided in Appendix-I together with ergot reactions. The susceptible checks ICH-105 and BJ-104 developed more than 40% smut. We selected 48 smut-free heads for further evaluation.

6.4.2 Initial Screen-B:- We screened 85 germplasm selections made by Clement in Upper Volta. Eighteen lines were smut-free, 28 lines had no more than 1% smut, and only 2 lines had more than 20% smut (Table 29). The detailed observations are presented in Appendix-II together with ergot reactions. We selected 36 smut-free heads for further evaluation.

6.4.3 Initial Screen-C:- We screened 654 selections in breeding lines from Upper Volta. About 7% of the entries (48 selections) were smut-free, about 17% of the entries (110 selections) developed no more than 1% smut. Only 27 entries (4% of selection) had more than 20% smut

(Table 30). The detailed reactions are provided in Appendix-III together with ergot reactions. We selected more than 300 smut-free heads for further testing.

6.4.4 ICRISAT Breeding materials:- A total of 99 entries from 5 trials were screened. These included hybrids, inbreds, hybrid-parents, ms-lines, and IPMAT-5 entries. The smut reactions of hybrids, hybrid-parents and ms-lines are presented in Appendix-IV together with ergot reactions and those of IPMAT-5 and inbre are presented in Appendix-XXVII and the summary presented in Table 31.

Of 23 inbreds, 6 were smut-free and 9 developed smut in the range of 0.1 to 5%. Among 21 IPMAT-5 entries, no entry was smut free, 12 entries had smut in the range of <1 to 20% and the remaining 9 entries developed more than 20% smut. Of 25 hybrid-parents, 19 entries developed smut in the range of <1-20%, and the remaining 6 had more than 20% smut.

Hybrids and the ms-lines were highly susceptible. Only 5 of the 27 hybrids had smut in the range of 10-20% and the remaining hybrids and the 3 ms-lines all had more than 20% smut.

6.5 Advanced Screen:-

Smut-free single head selections from the Initial Screen are retested as head-to-row progenies in the Advance Screen. About 800 entries were screened in 3 trials.

6.5.1 Advanced Screen-A:- Four of the 54 entries were smut-free, 25 entries developed smut in the range of 0.1-1% and the remaining entries had smut between 1 and 20% (Table 32) compared with 40% smut infection in the susceptible check lines . The detailed smut reactions are presented in Appendix-XVIII. We selected 60 smut-free heads from 29 promising entries for further evaluation.

6.5.2      Advanced Screen-B:- Of 525 entries screened, 104 entries were smut-free, 155 entries had smut between 0.1 and 1 percent, 149 entries had between 1.1 and 5% and only 18 entries had more than 20% smut (Table 33). The smut reactions of individual entries are presented in Appendix-XXIX. About 300 smut-free single heads were selected from 100 promising entries for further evaluation.

6.5.3      Advanced Screen-C:- Of the 211 entries, 58 were smut-free, 59 entries developed smut in the range of 0.1 to 1.0% and only 3 entries had more than 20% smut (Table 34). In Appendix-XXX smut reactions of individual entries are presented. About 150 smut free-single heads from 51 promising entries were selected for further evaluation.

6.5.4      Pearl Millet Smut Nursery (PMSN):- The 1979 PMSN with 28 promising entries from the 1978 Advanced Screen, was screened at Hissar. Five entries were smut-free, 11 entries had smut in the range of 0.1 to 1%, and the remaining entries developed smut in the range of 1 to 9% (Table 35). The 5 smut-free entries have been included in the 1980 IPMSN for multilocational testing.

#### 6.6      International Pearl Millet Smut Nursery (IPMSN):-

The 1979 IPMSN with 37 entries was tested at Dambey (Senegal), Kamboinse (Upper Volta), and Jamnagar and Hissar (India). The results were encouraging and five entries; ICI 7517-S-1, P-10-S-1, SSCPS 252-S-4, ED209-1-6-S-7, and P-20-S-1 were highly resistant to smut (no more than 4% smut at any one locations) across locations (Report of the 1979 IPMSN, PMPS 3001).

#### 6.7      Development of Smut Resistance:-

In an attempt to rapidly build-up high levels of smut resistance, the lines identified as apparently less susceptible to smut in the 1977 screening were intermated in the 1977-78 post rainy season. F<sub>1</sub> progenies were tested during the 1978 and the F<sub>2</sub> progenies were screened during the 1979 rainy season. Of 117 F<sub>2</sub> populations screened, 6 were smut-free, 37

populations developed smut in the range of 0.1 to 5%, and only 2 populations had more than 20% smut. Smut reactions of individual entries are presented in Appendices XXXI-XXXII. About 400 smut-free single heads were selected for testing as F<sub>3</sub> families in the 1980 rainy season.

6.3 Utilization of smut resistance

Smut resistance sources are being utilized in various ways in the breeding program.

- i) - two smut resistant lines were crossed with 27 agronomic elite lines by Dr. B.S. Talukdar in the 1977-78 post rainy season and 50 F<sub>1</sub> lines tested in the 1978 rainy season and F<sub>2</sub> populations were screened during the 1979 rainy season. Of 50 F<sub>2</sub> populations, 1 was smut-free and 44 populations had smut in the range of 0.1 to 10% and only 1 population had more than 20% smut. The smut reactions of individual populations are presented in Appendix-XXXIII. More than 100 smut-free single heads were selected for testing as F<sub>3</sub> lines as head-to-row progenies.
- ii) - On the 3 ms-lines 90 test crosses made by Dr. B.S. Talukdar with smut resistant lines to test their potential as pollinators. These test crosses will be screened during the 1980 rainy season.
- iii) - Smut resistant composite populations formed by Dr. S.C. Gupta with 37 smut less susceptible lines and progenies will be screened in the 1980 rainy season.
- iv) - F<sub>2</sub> populations from crosses between smut resistant and a high tillering, and dwarf line (made by Dr. K. Anand Kumar) will be screened during the 1980 rainy season.

a/ Mean of 10 bagged - inoculated heads

b/ Mean of 10 inoculated - bagged heads in smut nursery at Hissar

Appendix III

Ergot and Smut reactions and days to 75 percent flowering (DTF) of 651 Upper Volta selections in the initial screenings during the 1979 rainy season.

<sup>a/</sup> 10 of 20 bagged inoculated heads

<sup>b/</sup> Mean of 10 inoculated-bagged heads at Hissar

<sup>c/</sup>

Recorded in downy mildew nursery at ICRISAT Center

\* 84 ergot free heads were selected for further evaluation at the F<sub>5</sub> stage

## Appendix XVIII

Fert and smut reactions, and agronomic score and days to 75 percent flowering (DTF) or 214 F<sub>1</sub>-II lines during 1979  
rainy season at ICRISAT Center.

a/ Mean of 10 inoculated-bagged heads

b/ Screened during the 1978-79 post rainy season in the downy mildew nursery at ICRISAT Center.

c/ Based on 1-5 scale, scored during the 1978-79 post rainy season at ICRISAT Center.

\* Smut free heads selected for further testing.

Appendix XXX

Smut reactions and days to 75 percent flowering (DTF) of 211 entry Advanced smut screening-C during the 1979 rainy season at Hissar.
