PIGEOMPRA COLLECTION IN ATTAPPADI HILLS AND ATTLOSIA COLLECTION IN SILENT VALLEY, SOUTH INDIA (26 Jan-11 Peb 1981)

P. Remenendan*

1. OBJECTIVES

- (1) Collection of pigeonpea landraces from the Attappedi Hills of the Western Chets
- (2) Search for Atylogia species in Silent Valley and Biligiri Rangen Hills.

2. SUDMARY

The Attappedi Hills are known for pigeonpess of good quality for "dal". The ICRISAT game bank had no substantial representation from this area. During the present mission the entire pigeonpes growing area of this region was covered which resulted in securing a richly varied representative collection. In total, 39 samples were collected, some from adjoining areas, and field observations were made.

Pigeompeas of the Atteppedi Hills are late indeterminate cvs with mostly large white seeds. There is considerable variability in seed color pattern and pod characteristics. Many of them have high potential for the "vegetable type" pigeompea breeding and utilization.

Silent Valley is botanically little explored. The present search for <u>Atylosis</u> resulted in the collection of <u>Atylosis lineats</u>, <u>A. scarabasoides</u>, <u>A. goeneis</u>, and <u>Ebynchosis rothii</u> with plenty of ripe seeds. The vegetation of this undisturbed area is the richest in the Western Chats and the possibility of even more species occurring here certainly exists.

"Botamist (pigeonpes), Genetic Resources Unit, ICRISAT.

Apart from this, ripe seeds of <u>Atylogia trinervia</u> and <u>Dumberia</u>

<u>ferrugines</u> were collected from the Hilgiri hills. On the way back the route
through the Biligiri Rangan Hills of Karnataka yielded ripe seeds of <u>Atylogia</u>
<u>albicans</u> and <u>Rhynchogia rothii</u>. <u>Rhynchogia suaveolena</u> and <u>R. heynei</u> were
also located in the protected forests of B.R. Hills, but the seeds could not
be obtained as these mature early. The first week of January is the right
time to collect in B.R. Hills.

3. PLANNING

3.1. Time and Area of collection

Information on the pigeonpea growing areas of Attappadi Hills was gathered during an earlier visit of nearby hills. The late cvs grown in this area mature during January end. Hence the collecting time was planned to coincide with the harvast period.

Silent Valley is located in the Attappadi Hills. This being a botanically little explored area there is no record of the occurrence of <u>Atylosia</u>
here. However, from our experience of the distribution of <u>Atylosia</u> species
and their ecological preference, we expected several species here. Search
for <u>Atylosia</u> in Silent Valley could be combined with the pigeonpea collection
in Attappadi Hills, as the period of collection was just the right time to
collect <u>Atylosia</u> seeds in ripe stage as based on our previous experience in
the adjoining Wilgiri Hills and Bendipur-Hudumalai forests.

It was further planned to return through the Milgiri Hills of the adjoining area and Biligiri Rangan Hills of Karnataka, to visit more locations of <u>Atvlosia</u>.

Contacts were established with the Forest Department of Kerala for obtaining permission to visit Silent Valley, which is no longer open to the public without prior sanction.

3.2. Collecting Team

- P. Remanandan, Botanist, Genetic Resources Unit
- H.S.M.I. Biyabami, Driver-cum-General Assistant, Genetic Resources Unit

3.3. Itinerary

- January 26 Hyderabad Bangalore.
 - 27 Bengalore Kanakapura Malvalli Mysore Hampapura Manamtavadi Kalpetta.
 - 28 Kalpetta Calicut Manjeri Mannaraghet Mukkeli.
 - 29 Nukkali Anakatti Hukkali.
 - 30 Hukkali Hannaraghet Mukkali.
 - 31 Mukkeli Silent Valley Mukkali.
- February I Mukkali Pollachi Mukkali.
 - 2 Mukkali Pedagiri Mukkali.
 - 3 Mukkali Silent Valley Mukkali.
 - 4 Mukkali Minakshipuran.
 - 5 Minakshipuram Malappuram.
 - 6 Malappuram Mamjeri Milambur Gudalur Ootacamund.
 - 7 Octacamund Dodabetta Octacamund.
 - 8 Octacamund.
 - 9 Ootscamund Coonoor Nettuppalayam Satyamangalam.
 - 10 Satyanengalam Dimbam Bailur Kollegal Malvalli Maddur Bangalore.
 - 11 Bangalore Hydersbad.

A. HIGHLIGHTS

4.1. Pigeompeas of Attappadi Hills

The Attappadi Hills are located in the northeastern corner of Palghat district of Kerala and on the northeastern side of Coimbatore district of Tamil Madu. It descends like an extended cliff from the Milgiri plateau which is to the north. Facing the Arabian sea, these hills receive the full blast of the southwest moneoon. In a span of 3-4 months they have a rainfall of 5000-6000 mm. In contrast, the eastern side receives only around 400 mm of rain.

From the southwest monsoon the area receives rain from June to September. June—July is the peak period declining from August to September. During September—December the area receives rain from the northeast monsoon.

Paddy is cultivated throughout this area in the valleys. Mostly two crops are taken: in June—October and in November—March. Other crops grown include pigeonpea, black gram, cotton, cassava, and sorghum. Groundnut, chickpea, and finger millet are grown in limited areas. Thavalam, a village between Mukkali and Annakkatti grows groundnut. My attempt to secure seeds from farmers' houses was only partially successful, as many of them do not store the seeds. The crop is grown in considerable area in the hilly region of Palghat district and needs to be collected. It is sown in May, often inter-cropped with pigeonpea, and is harvested during October. Some samples of finger millet could be obtained from farmers' stores. Many farmers plant the millet in the pigeonpea—groundnut field after the harvest of groundnut.

The Attappadi pigeonpea is very popular in Kerala and adjoining
Tamil Nadu as the housewives prefer its "dal" for making "sambar". A consistent
character of almost all the samples collected from this area is the high seed
weight (Table-1) and the white seed coat. They are late cvs with indeterminate
growth habit. However, considerable variability exists in branching pattern,
pod and seed color pattern. The incidence of diseases and pests was rather
low.

Pigeonpea is usually sown on the onset of Southwest monsoon. It is grown either as a garden crop or in small fields intercropped with cereals or groundnut. January end is the harvest time. It was striking to note that the early cvs with smaller seeds grown in the adjoining Combatore district are never found in this hilly region. I learned from one of the progressive farmers that the early cvs do not fare well here, probably because they mature before the rains cease.

We went deep inside the village areas in all directions and obtained a truly representative collection. Some of the fields were very impressive and this collection should broaden the base for the breeding of vegetable pigeompeas as well as for improvement of "dal" quality.

4.2. Atylogia in Silent Valley, Kerela

Silent Valley, in the Palghat district is a part of the extensive, though broken, stretch of Western Ghat forests, which once extended from the Mahendragiri hills in Kanyakumari district to Goa as a massive green belt. Now the Silent Valley forest covers only less than 9,000 ha. It descends from a height of 2,520 m to 150 m across a distance of 3-4 km. Its steep slopes and numerous hills and gorges have enabled it to escape human interference till recent times. The warm climate and peculiar geological features that result in unusually prolonged period of abundant rain have resulted in the evolution and preservation of an exceptionally rich living gene bank and hence this forest enjoys a unique position in Southeast Asia.

Being an almost unexplored area, the floristic composition of Silent Valley has not been fully understood. However, several Atylosia species were reported and still occur in the Western Ghats and therefore we believe that this is an important area for the evolution and diversification of Atylosia. Several species of Atylosia and related genera like <u>Dumbaria</u> and <u>Rhynchosia</u> have been collected from the forests with comparable topographical and environmental situations during earlier missions undertaken in Western Ghats (GRU Progress Reports 4, 17, 20).

We searched for Atylosia and related genera from Mukkali to Silent
Valley Dam site. Mukkali is a small village located about 25 km from Silent
Valley. Tribals like Kurumban, Mudukan, Irlas, and new settlers, inhabit
this village. The Karala Government has a farm for the upliftment of
tribals at Chindakki. Mukkali is more or less completely deforested for
cultivation of paddy in the low land and in upland pigeonpes, black gram,
cotton, sorghum, horse gram, sugar-came, finger millet, banana, cassava, etc.,
are cultivated. The Bhavani River is the main source of irrigation for rice.
Kumtipuzha, a tributary of the Bharatapuzha, originating in the Silent
Valley, runs north-south, and reaches the Mannaraghat plains after a course
of about 30 km through the mountain ranges. These hills are covered by virgin
forests and here we searched for Atylosia spp. ...6.

We collected Atylogia sparabagoides from Makkeli with ripe seeds. However, the species is not very common here. From Mukkali to the Silent Valley dam site is a distance of about 25 km. The road passes through the heart of rainforest. Atylogia linests was in full bloom and fruiting stage in a wast region in Silent Velley. We secured alenty of ripe seeds and specimens. Our efforts to penetrate deep inside the rainforest were not always very successful due to the danger of wild animals (perticularly elephants) which were freely wandering around even at daytime. At one occasion we almost bumped into a pair of leopards. The rainforest is thoroughly infested with leaches, particularly the species with a white spot on head is very dangerous. Also we came across the famous lion-tailed monkey of Silent Valley. The rare animal, which is now restricted to a few pockets of the world, can be distinguished from the Wilgiri langur by its broad face and short tail. Atylogia goessis was located at one spot in flowering stage. Most of the pods were still green but we could get a few ripe seeds. The precise location of the species is given in the Table. Rhynchosia rothii too was collected from the same location with plenty of meture seeds. Desmodium rufescens, Vernonia divergens, V. cineres, Justicia procumbens, etc. grow abundantly in this location.

4.3. Milgiri Hills, Tamil Madu

The Milgiri Hills are the northernmost meeting point of the Western Chats and the Eastern Chats. While coming we passed through the Milgiri-Wynaad tract which is full of semi-tropical and deciduous lands interspersed with stunted shole growths. On return we took the route through Octacamumd-Coomoor where the climate is salubrious un the plateau. The Moyar in the north and the Bhavani in the south are the main rivers draining these hills. The area gets heavy rains from the Southwest and the Mortheast monsoons. Devala on the Gudalur side receives the highest rainfall (over 3000 mm) and is called the "Cherrapunji" of the south. However, most of the natural flora of this region has been replaced by industrial plantations or secondary forests.

The main food crops grown are rice, finger millet, wheat, and potatoes.

About 22,000 ha are under tea med coffee plantation occupies over 8200 ha.

Eucalyptus and Wattle plantations have replaced most of the remaining area of natural forests, and these secondary forests hardly support any vegetation undermeath.

We collected Atylogia trinervia from Doddabetta, the highest peak (2600 m) of Tamil Nadu, near Octy. The search for the species at other locations around Octy was not successful. The species appears to have been wiped out at many locations of lower altitudes and is now restricted to a very few places. So far we could not locate it at any other place in India and the accession which Dr. L.J.G. vem der Massen collected from Bri Lanka in 1980 from 1000 m altitude is strikingly different in morphology from the one thriving in the high altitude of Nilgiris. More accessions of the species need to be salvaged before their extinction.

<u>Dumbaria ferruginea</u> was collected from Coomoor-Mettuppalayam road where it is fairly common. This area has a good vegetation. The steep slopes have prevented the cultivation of the land which is otherwise very fertile.

4.4. Biligiri Rengen Hills, Kerneteka

These hills of Mysore district are isolated from both the Western and Eastern Ghats. They receive both the northeast and southwest monsoon rains. At foothills occur dry deciduous forests, at the top wet evergreen forests and in between the moist deciduous forests. The land has not yet been much exploited for large scale cultivation. However, grazing, indiscriminate timber felling, shifting cultivation, and forest fires have reduced the richness of the flore.

Atylogia rusosa has been reported from this area by earlier emplorers, apart from some <u>Mhynchosia</u> species and <u>Paracalyn</u>. However, we were a bit late for these species. The climate is much warmer and hence these species mature early. Biligiri Rangan betta and the surrounding areas, from where <u>Atylogia</u> species have been reported, were searched, but we could not locate <u>A. rusosa</u>. Biligiri Rangan betta is granitic with large boulders forming the hill. The vegetation in this area is of the moist deciduous and wet evergreen types with <u>Terminalia tomentosa</u> as the most dominant tree. Other common trees are <u>Allophyllus rheedi</u>, <u>Sterculia guttata</u>, <u>Sysygium cumini</u>, etc. <u>Common shrubs</u> are <u>Indigofera wightii</u>, <u>Murraya paniculata</u>, <u>Solanum torvum</u>, <u>Lantana camara</u>, <u>Acacia</u> pennata, etc.

Our search for <u>Atylosia</u> was limited to the roadside as the time was limited and also because the srea has a very large population of elephants. Wild elephants were found almost everywhere, and when they hide between clumps of the giant bamboo (<u>Dendrocalamus strictus</u>) it is not even easy to notice them.

We could not locate the main target species of this area, Atylosia rugosa, but while looking for it, we did collect Atylosia albicans and Rhynchosia rothii with ripe pods. Atylosia albicans had already shattered the seeds like most other legumes here. However, we could secure a few seeds. We collected two interesting other Cajaninae from here during this process without securing the seeds. They are tentatively identified as Rhynchosia susveolens and R. beynei on the basis of vegetative characters. The pracise locations of these species are given in the Table 1. The seeds of these species need to be secured. Late December-early January should be the right time.

From the short time I spent in this area I felt that this is an area which is rich in <u>Cajeninae</u> and needs to be re-explored in more detail. But as mentioned earlier these reserved forests have a rich variety of wild snimals and one has to be extremely cautious of the elephants, which move freely even during daytime.

 Profusely branching indeterminate pigeonpea covering the area vacated by cereals, Attappadi Hills, Kerala.

). Variation in seeds per pod and pod colour pattern

Vegetable type pigeonpea of Attappadi Hills

Atylogia lineata in Silent Valley.
