There is an increasing international market for extra-large (>50g 100-seed⁻¹) kabuli chickpea. Such chickpeas are being sold at about three times the price of desi chickpea and about two times the price of medium-seeded (~25 g 100 seed⁻¹) kabuli chickpea in India, the largest chickpea importing country. None of the kabuli chickpea varieties released to date in India has seed size larger than 40 g 100 seed⁻¹. Thus, the Government of India has launched a 3-year project from 1 April 2006 on breeding extra-large kabuli chickpea with resistance to fusarium wilt under the Integrated Scheme of Oilseeds, Pulses, Oil Palm and Maize (ISOPOM).

Fusarium wilt (FW), caused by *Fusarium oxysporum* f. sp. *ciceri*, is the most important root disease of chickpea in the semi-arid tropics (SAT), where the chickpea growing season is dry and warm. Resistance to FW is required in all chickpea cultivars targeted for SAT and other FW-prone areas of the world. There are many sources with high resistance to FW available in desi type, while resistance sources in kabuli type are limited. A world collection of over 13,500 germplasm accessions from 40 countries was evaluated for race 1 of *Fusarium oxysporum* at ICRISAT-Patancheru. Of the 160 resistant accessions identified, only 10 accessions were of kabuli type (Haware et al. 1992). Desi × kabuli crosses have been widely used at ICRISAT for enhancing FW resistance of kabuli chickpea. However, most kabuli varieties that involved one or more desi parents in the pedigree have a brown tinge in seed color, e.g. Swetha (ICCV 2), KAK 2 (ICCV 92311), JGK 1 (ICCV 92337), and Vihar (ICCV 95311), while the market prefers cream to white (zero tannin) seed color in kabuli chickpea. Thus, it is important to identify additional sources of FW resistance in kabuli chickpea, particularly in the large-seeded category, so that large-seeded kabuli varieties with high resistance to FW and typical kabuli type seed (ram's head shape and white seed color) can be developed from kabuli × kabuli crosses.

We selected 50 large-seeded kabuli chickpea germplasm from ICRISAT's genebank and evaluated these for agronomic traits at ICRISAT-Patancheru during the 2004/05

postrainy season. From these, 12 accessions having seed size larger than 50 g 100 seed⁻¹ were selected for further evaluation. During the 2005/06 postrainy season, one set of these 12 genotypes was grown in wilt-sick plot for screening against FW and another set in wilt-free area for evaluation of agronomic traits.

Two accessions, ICC 14194 and ICC 17109, originating from Mexico, showed complete resistance (0% plant mortality) to FW, whereas other lines showed 11–100 % plant mortality (Table 1). The resistant control (WR 315) had 0% plant mortality, whereas the early-wilt susceptible check (JG 62) had 100%, and the late-wilt (K 850) susceptible check had 87% mortality. Both the resistant accessions had pinnate (fern) leaves, which is the common leaf type in chickpea. ICC 14194 was very early (97 days), while ICC 17109 had medium maturity (115 days). A comparison of the seeds of a medium-seeded variety ICCV 2 (25 g 100 seed⁻¹), a large-seeded variety KAK 2 (38 g 100 seed⁻¹) and an extra-large-seeded kabuli line ICC 17109 (63 g 100 seed⁻¹) is shown in Figure 1.

Early maturity is important in chickpea for its adaptation to short-season environments and for escape from terminal drought, which is the number one constraint to chickpea productivity in the SAT. The development of medium- to large-seeded (25–40 g 100 seed⁻¹) early-maturing kabuli varieties, particularly ICCV 2 and KAK 2, has helped expansion of kabuli chickpea area to southern India, which has typically short-season tropical environment (Gowda and Gaur 2004). Of the 12 accessions evaluated in this study, two (ICC 14194 and ICC 14198) were very early (days to maturity <100 days) and had 50–53 g 100 seed⁻¹, suggesting that it is possible to breed early-maturing kabuli varieties with extra-large seed.

It is hoped that these new FW resistance sources will be very useful in breeding extra-large kabuli varieties with FW resistance and typical kabuli type seed. The seeds of these accessions are available for distribution at ICRISAT's genebank.
